Abstract
In this paper we study the existence of periodic travelling waves for the 2D $abcd$ Boussinesq type system related with the three-dimensional water-wave dynamics in the weakly nonlinear long-wave regime. Small solutions that are periodic in the direction of translation form an infinite-dimensional family, by characterizing them using a center manifold reduction of infinite dimension and codimension due to the fact that at the linear level we are dealing with an ill-posed mixed-type initial-value problem. As happens for the Benney-Luke model and the KP II model for wave speed large enough and large surface tension, we show that a unique global solution exists for arbitrary small initial data for the two-component bottom velocity, specified along a single line in the direction of translation (or orthogonal to it). As a consequence of this fact, we show that the spatial evolution of bottom velocity is governed by a dispersive, nonlocal, nonlinear wave equation.

Keywords: Water wave model, periodic travelling waves, center manifold reduction
1 Introduction

In this paper we consider the study of $x$-periodic travelling waves for a 2D nonlinear water waves system where the transverse spatial direction to the propagation $y$ is unbounded. The main idea is to perform a center manifold reduction by rewriting the 2D water wave system as an (ill) evolutionary equation

$$u_\zeta = A(u) + G(u), \quad (1.1)$$

where an unbounded spatial coordinate plays the role of the timelike variable $\zeta$ (see Kirchgässner [7]). For the Boussinesq system considered in this work, we are able to describe all small waves that translate steadily with wave speed large enough (supercritical), that are $x$-periodic in the direction of translation. We will see that these solutions in fact form an infinite-dimensional family which can be parametrized by the bottom-velocity profile along any single line in the direction of translation. In other words, for a fixed wave speed large enough (supercritical) and an arbitrary bottom-velocity data small in a suitable Sobolev space, there corresponds a unique global $x$-periodic travelling wave, as happens with the linear wave equation driven by

$$\eta_{tt} = \eta_{xx} + \eta_{yy},$$

where $\eta$ corresponds to the surface elevation. In this simple case, there are many travelling wave solutions $\eta = f(x - \omega t, y)$ translating with supercritical speed $|\omega| > 1$ that appear by solving the wave equation $f_{yy} = (\omega^2 - 1)f_{\xi\xi}$ with given arbitrary initial data for the wave slope $(\eta_x, \eta_y)$ along the single line $y = 0$. On the other hand, in the case of the exact linearized water wave equations for an inviscid irrotational fluid without surface tension, and the Kadomtsev-Petviashvili equation in the KP-II case, it is known that an arbitrary small data for wave slope along a line determines a unique travelling wave with given supercritical speed (see [17]). This is also the case for the Benney-Luke equation since J. Quintero and R. Pego in ([1]) showed that a complete $x$-periodic travelling wave solution is determined uniquely by arbitrarily specifying the horizontal velocity $(\Phi_x, \Phi_y)$ along $y = 0$ at the fluid bottom, provided the smallness of the initial data in an appropriate norm (the $H^1$ Sobolev norm).

In this paper we consider the existence of non trivial $x$-periodic travelling wave for the 2D $abcd$-Boussinesq system related with the water wave problem

$$\begin{cases}
(I - b\mu\Delta)\Phi_t + (I - a\mu\Delta)\eta + \frac{\mu}{\mu + 1} (\Phi_x^{p+1} + \Phi_y^{p+1}) = 0, \\
(I - d\mu\Delta)\eta_t + \Delta\Phi - c\mu\Delta^2\Phi + \epsilon \nabla \cdot (\eta (\Phi_x^p, \Phi_y^p)) = 0,
\end{cases} \quad (1.2)$$

where $b + d - a - c = \frac{1}{3} - \sigma$, with $a, b, c, d > 0$, $\sqrt{\mu} = \frac{b}{d}$ is the ratio of undisturbed fluid depth to typical wave length (long-wave parameter or dispersion
coefficient), and $\epsilon$ is the ratio of typical wave amplitude to fluid depth (amplitude parameter or nonlinearity coefficient), $\sigma$ is associated with the surface tension ($\sigma^{-1}$ is the Bond number), $\Phi$ is the rescale nondimensional velocity potential on the bottom $z = 0$, and $\eta$ is the rescaled free surface elevation. We consider waves which are periodic in a moving frame of reference, so that they are $x$-periodic in the variable $x - \omega t$, where $t$ denotes the temporal variable. For this physical problem, we have a bounded spacelike coordinates (the vertical direction), which is bounded because the fluid has finite depth, and the coordinate $x - \omega t$ which is considered bounded because we are looking for periodic wave in this variable. Due to the fact that there is not any restriction upon the behavior of the waves in the spatial direction $y$ transverse to their direction of propagation, we are allowed to use $y$ as the timelike variable. We apply spatial dynamics to the problem by considering the travelling wave system as an evolutionary system of the form (1.1) with $\zeta = y$ in an infinite-dimensional phase space consisting of periodic functions of $x - \omega t$ (see Groves and Schneider [5], Sandstede and Scheel [11], [12], and Haragus-Courcelle and Schneider [6] for applications to respectively nonlinear wave equations, reaction-diffusion equations, and Taylor-Couette problems, Quintero and Pego [1] for periodic nonlinear travelling for the Benney-Luke model).

In the case of wave speed $|\omega| > 1$ and $\sigma > \frac{1}{2}$ (large surface tension), the $abcd$-Boussinesq system (1.2) under consideration has a very close relationship with the Benney-Luke model derived by J. Quintero and R. Pego in [2] when $\tilde{a} - \tilde{b} = \sigma - \frac{1}{3} > 0$ and also with the KP-II model ($\sigma > \frac{1}{4}$), in the sense that travelling waves for the Boussinesq system (1.2) can generate travelling waves for the Benney-Luke model and the KP-II model, up to some order. Moreover, for large wave speed and large surface tension, the $abcd$-Boussinesq system (1.2), the Benney-Luke model and the KP II model share ill-posed spatial evolution equations with infinite-dimensional center manifolds, where the dimension of the center manifold is determined by the number of purely imaginary eigenvalues (e.g., see Vanderbauwhede [16]). Existence of invariant center manifold of infinite dimension and codimension under special hypotheses has been established for infinite-dimensional evolutionary systems, showing in particular that the original problem is locally equivalent to a system of ordinary differential equations whose solutions can be expressed in terms of the solution on the center space (tangent to the center manifold), see for example works by Scarpellini [13], [14], Mielke [9] and Vanderbauwhede and Iooss [15], Quintero and Pego [1], among others. In the $abcd$-Boussinesq, existence of an infinite dimensional invariant center manifold for which the spectrum of hyperbolic space is unbounded on both sides of the imaginary axis is a direct consequence of the work by J. Quintero and R. Pego [1] (see also [7, 8, 10]).

In this paper, we describe all small travelling waves that translate steadily, which are periodic in the direction of translation (or orthogonal to it), in the
case of supercritical speed $|\omega| > 1$ and some restriction on the coefficients $a, b, c, d$. In this regime, after rescaling $\epsilon$ and $\mu$, the traveling-wave system for (1.2) takes the form

\[
\begin{pmatrix}
-\omega(I - d\Delta)u_x + (I - c\Delta)\Delta v + \nabla \cdot \left( u \left( v^p_x, v^p_y \right) \right) \\
-\omega(I - b\Delta)v_x + (I - a\Delta)u + \frac{1}{p+1} \left( v^{p+1}_x + v^{p+1}_y \right)
\end{pmatrix}
= \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\]

(1.3)

Existence of periodic travelling waves follows by considering the system (1.3) as an evolution equation likewise (1.1), where $y$ acts as the “time” variable. If we seek for $x$-periodic travelling wave solutions, the initial-value problem for the system (1.3) considered as an evolution equation in the variable $y$ has mixed type due to the fact that the Cauchy problem turns out to be linearly ill-posed for wave speed $|\omega|$ large enough and under some conditions on $a, b, c$ and $d$. We will see that at the linear level there are infinite many central modes (pure imaginary eigenvalues) and infinitely many hyperbolic modes, and also that there is a spectral gap since the hyperbolic nodes are located outside of a strip containing the imaginary axis. As a consequence of this fact, the existence result of $x$-periodic travelling wave solutions involves using an invariant center manifold of infinite dimension and infinite codimension. This center manifold contains all globally defined small-amplitude solutions of the travelling wave equation for the Boussinesq system that are $x$-periodic in the direction of propagation.

We point out that the dynamics for the $abcd$-Boussinesq system in the case $a, c > 0$ and $b = d = 0$ is quite different from the case $a, b, c, d > 0$ in the sense that in the first case, at the linear level, there are only finite many central modes (pure imaginary eigenvalues) and infinitely many hyperbolic modes (see [3]).

The main result of this paper involves using the fact that there exists an invariant center manifold of infinite dimension and codimension that contains all globally defined small-amplitude solutions of (1.3) that are periodic in the direction of propagation. These solutions are determined by suitable initial data along the line $y = 0$. In particular, we show that a complete traveling wave solution of (1.3) is determined uniquely by arbitrarily specifying along $y = 0$ the horizontal velocity $(\Phi_x, \Phi_y)$ at the fluid bottom, provided these data are sufficiently small in an appropriate norm (the $H^1$ Sobolev norm). The bottom-velocity profile evolves in $y$ according to a dispersive, nonlinear, nonlocal wave equation obtained by restriction to the two first components to the invariant center manifold of the form

\[
\frac{d}{dy} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \begin{pmatrix} 0 & \partial_x \\ S\partial_x & 0 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + \begin{pmatrix} 0 \\ g(u_1, u_2) \end{pmatrix},
\]

in which the map $g$ is Lipschitz with $g(0) = 0$, $Dg(0,0) = 0$, and $S$ is a nonlocal linear operator of zero order.
2 Existence of a local center manifold

The goal in this section is to verify the hypotheses of an abstract center manifold result obtained by J. Quintero and R. Pego in [1] (Theorem 2.1 in the Appendix) to get the existence of a local center manifold associated with travelling waves for $abcd$-Boussinesq system, viewed as a first order system (2.3) with the variable $y$ being the timelike variable. We will show for the system (2.3) associated with the $abcd$-Boussinesq system the existence of a locally invariant center manifold of classical solutions, where the center subspace (that associated with the purely imaginary spectrum of $A$) has infinite dimension and infinite codimension, as happens for the Benney-Luke model (see [1]).

Hereafter, for a given integer $r \geq 0$, let $\tilde{H}^r$ denote the Sobolev space of $2\pi$-periodic functions on $\mathbb{R}$ whose weak derivatives up to order $k$ are square-integrable with norm given by

$$\|u\|_{\tilde{H}^r}^2 = \sum_{j=0}^{r} \int_0^{2\pi} |\partial_x^j u|^2 dx.$$ 

We will study the existence of $x$-periodic solutions for (2.3) in the Hilbert spaces $H$ and $X$ defined by

$$H = \tilde{H}^1 \times \tilde{H}^1 \times \tilde{H}^0 \times \tilde{H}^{-1} \times \tilde{H}^1 \times \tilde{H}^0,$$

$$X = \tilde{H}^2 \times \tilde{H}^2 \times \tilde{H}^1 \times \tilde{H}^0 \times \tilde{H}^1 \times \tilde{H}^0.$$ 

Note that $X$ is densely embedded in $H$.

2.1 Periodic travelling wave for the $abcd$-Boussinesq system

Recall that $x$-periodic travelling-wave profile $(u, v)$ should satisfy the system (1.3). In order to look for the existence of $x$-periodic travelling waves of period $2\pi$, we set the new variable $U^t = (u_1, u_2, u_3, u_4, u_5, u_6)$, where

$$u_1 = \partial_x v, u_2 = \partial_y v, u_3 = \partial_{yy} v, u_4 = \partial_{yyy} v, u_5 = u, u_6 = \partial_y u.$$
If we set $\gamma c = 1$ and $ac\alpha = 1$, $\alpha_1 = ad\omega^2 - \gamma$, $\alpha_2 = abd\omega^2 - 1$, $\alpha_3 = abd\omega^2 - 2$, and $\alpha_4 = \omega(\gamma - ad)$, we have that

$$
\begin{align*}
\partial_y u_1 &= \partial_x u_2 \\
\partial_y u_2 &= u_3 \\
\partial_y u_3 &= u_4 \\
\partial_y u_4 &= -\alpha_3 \partial_x u_1 + \alpha_2 \partial_{xxx} u_1 + \gamma u_3 + \alpha_3 \partial_{xx} u_3 - \omega \alpha_4 \partial_x u_5 \\
&\quad + \gamma (u_5 u_1^p) x + \gamma (u_6 u_2^p + pu_5 u_2^{p-1} u_3) + \frac{ad\omega}{p+1} \partial_x (u_1^{p+1} + u_2^{p+1}) \\
\partial_y u_5 &= u_6 \\
\partial_y u_6 &= -\omega c\alpha u_1 + b\omega c\alpha \partial_{xx} u_1 + b\omega c\alpha \partial_x u_3 + \alpha c u_5 - \partial_{xx} u_5 \\
&\quad + \frac{ac}{p+1} (u_1^{p+1} + u_2^{p+1}) .
\end{align*}
$$

(2.1)

In terms of the new variable $U$, we see that this system can be rewritten as an evolution in which $y$ is considered as the time variable

$$
\partial_y U = AU + G(U),
$$

(2.3)

where the linear operator $A$ and the nonlinear term $G$ are given by

$$
A = \begin{pmatrix}
0 & \partial_x & 0 & 0 & 0 & 0 \\
0 & 0 & I & 0 & 0 & 0 \\
0 & 0 & 0 & I & 0 & 0 \\
-\alpha_3 \partial_x + \alpha_2 \partial_{xxx} & 0 & \gamma I + \alpha_3 \partial_{xx} & 0 & -\alpha_4 \partial_x & 0 \\
0 & 0 & 0 & 0 & 0 & I \\
-\omega c I + b\omega c\alpha \partial_{xx} & 0 & b\omega c\alpha \partial_x & 0 & \alpha c I - \partial_{xx} & 0
\end{pmatrix}
$$

and also

$$
G(U) = \begin{pmatrix}
0 \\
0 \\
0 \\
\gamma (u_5 u_1^p) x + \gamma (u_6 u_2^p + pu_5 u_2^{p-1} u_3) + \frac{ad\omega}{p+1} \partial_x (u_1^{p+1} + u_2^{p+1}) \\
\frac{ac}{p+1} (u_1^{p+1} + u_2^{p+1})
\end{pmatrix}.
$$

If we assume that $U(x; y) = \sum_{n \in \mathbb{Z}} \hat{U}(n, y)e^{inx}$, then we see that

$$
\partial_y \hat{U}(n) = \hat{A}(n)\hat{U}(n, y) + \hat{G}_n(U),
$$
where the matrix $\hat{A}(n)$ has the form

$$
\hat{A}(n) = \begin{pmatrix}
0 & in & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
-ina_1 - in^3a_2 & 0 & \gamma - n^2a_3 & 0 & -ina_4 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
-\omega c - n^2b\omega c & 0 & inb\omega c & 0 & c\omega & 0 + n^2 & 0
\end{pmatrix}.
$$

It is straightforward to see that the characteristic polynomial $P(n,\beta)$ of $\hat{A}(n)$ is given by

$$
P(n,\beta) = \beta^6 + a_2(n)\beta^4 + a_1(n)\beta^2 + a_0(n),
$$

where $a_0(n)$, $a_1(n)$ and $a_2(n)$ are defined as

$$
a_2(n) = (abd\omega^2 - 3)n^2 - (c\omega + \gamma),
$$

$$
a_1(n) = (3 - 2abd\omega^2)n^4 + (2(c\omega + \gamma) - \alpha\omega^2(b + d))n^2 + \alpha,
$$

$$
a_0(n) = n^2[(abd\omega^2 - 1)n^4 + (\alpha(d\omega^2 - c) + \gamma(bc\omega^2 - b))n^2 + \alpha(\omega^2 - 1)].
$$

We note that the eigenvalues for $\hat{A}(n)$ are roots of the cubic polynomial $p_n$ in the variable $\lambda = \beta^2$ given by

$$
p_n(\lambda) = \lambda^3 + a_2(n)\lambda^2 + a_1(n)\lambda + a_0(n).
$$

### 2.2 Structural conditions

We first consider the basic structural conditions. It is straightforward to check that $A \in \mathcal{L}(X,H)$, where $\mathcal{L}(X,H)$ denotes the space of bounded linear operators from $X$ to $H$. It is easy to check for $U,V \in H$ that

$$
\|G(U + V) - G(U)\|_X \leq (\|U\|^p_H + \|V\|^p_H)\|V\|_H.
$$

In other words, $G: H \to X$ is smooth, and clearly $G(0) = 0 = DG(0)$, meaning that the nonlinear map $f$ exhibits a gain of regularity. We will exploit this feature to establish the existence of classical solutions.

### 2.3 Spectral decomposition

We will construct the desired spectral decompositions of $H$ and $X$ by using a complete set of eigenfunctions built via Fourier series. First, we see that any element $U \in H$ or $X$ can be represented by a Fourier series

$$
U = \sum_{n \in \mathbb{Z}} \hat{U}(n)e^{inx}.
$$
In terms of the vector of the Fourier coefficients, the norms in $H$ and $X$ may be given by
\[ \|U\|_H^2 = \sum_{n \in \mathbb{Z}} |S_H(n)\hat{U}(n)|^2, \quad \|U\|_X^2 = \sum_{n \in \mathbb{Z}} (1 + n^2)|S_H(n)\hat{U}(n)|^2, \]
where
\[ S_H(n) = \text{diag}\left\{ (1 + n^2)^{\frac{1}{2}}, (1 + n^2)^{\frac{1}{2}}, 1, (1 + n^2)^{-\frac{1}{2}}, (1 + n^2)^{\frac{1}{2}}, 1 \right\}. \]

**Right and left eigenvectors of $\hat{A}(n)$**

For $n = 0$, we have that
\[ p_0(\lambda) = \lambda^3 - (c\alpha + \gamma)\lambda^2 + c\alpha\gamma\lambda = \lambda(\lambda - c\alpha)(\lambda - \gamma). \]
So, we conclude that $\lambda = 0$, $\lambda = c\alpha$ and $\lambda = \gamma$. It can be seen that $\beta_1(0) = \beta_2(0) = 0$ is a double zero of $\mathcal{P}(0, \beta)$, and $\beta_3(0) = \sqrt{\gamma} = -\beta_4(0)$ and $\beta_5(0) = \sqrt{c\alpha} = -\beta_6(0)$ are simple roots of $\mathcal{P}(0, \beta)$. We see directly that the eigenvectors are
\[ v_1(0) = (1, 0, 0, 0, \omega, 0)^t, \quad v_2(0) = (0, 1, 0, 0, 0)^t, \]
and left eigenvectors
\[ z_1(0) = (1, 0, 0, 0, 0, 0)^t, \quad z_2(0) = (0, 1, 0, -c, 0, 0)^t. \]

The eigenvalue $\beta_3(0) = \sqrt{\gamma} = -\beta_4(0)$ are single eigenvalues with right eigenvectors
\[ v_3(0) = \left( 0, 1, \sqrt{\frac{1}{c}}, \frac{1}{c}, 0, 0 \right)^t, \quad v_4(0) = \left( 0, 1, -\sqrt{\frac{1}{c}}, \frac{1}{c}, 0, 0 \right)^t, \]
and left eigenvectors
\[ z_3(0) = \frac{c}{2} \left( 0, 0, \sqrt{\frac{1}{c}}, 1, 0, 0 \right)^t, \quad z_4(0) = \frac{c}{2} \left( 0, 0, -\sqrt{\frac{1}{c}}, 1, 0, 0 \right)^t. \]

On the other hand, the eigenvalues $\beta_5(0) = \sqrt{c\alpha} = -\beta_6(0)$ are single eigenvalues with right eigenvectors
\[ v_5(0) = \left( 0, 0, 0, 0, 1, \sqrt{\frac{1}{a}} \right)^t, \quad v_6(0) = \left( 0, 0, 0, 0, 1, -\sqrt{\frac{1}{a}} \right)^t, \]
and left eigenvectors

\[ z_5(0) = \frac{\omega}{2} \left(1, 0, 0, 0, \frac{1}{\omega}, \sqrt{a} \right)^t, \quad z_6(0) = \frac{\omega}{2} \left(1, 0, 0, 0, \frac{1}{\omega}, -\sqrt{a} \right)^t. \]

Assume now that \( n \neq 0 \). We will see that the polynomial \( p_n \) has a negative real root \( \lambda_1(n) \) for any \( n \neq 0 \) and for

\[ \omega^2 > \max \left\{ 1, \frac{c}{d}, \frac{1}{\alpha bd}, \frac{1}{abc} \right\} = \max \left\{ 1, \frac{c}{d}, \frac{ac}{bd}, \frac{a}{b} \right\} := \omega_0^2(a, b, c, d) \]

with \( w_0 > 0 \ (b, d > 0) \). In fact, in this regime, we have that \( a_0(n) > 0 \) for \( n \neq 0 \) and so, \( p_n(0) = a_0(n) > 0 \), meaning that \( p_n \) must have a negative real root \( \lambda_1(n) < 0 \). On the other hand, note that

\[ p'_n(\lambda) = 3\lambda^2 + 2a_2(n)\lambda + a_1(n) \]

has roots given by

\[ \rho_+(n) = -\frac{a_2(n)}{3} + \frac{\sqrt{a_2^2(n) - 3a_1(n)}}{3}, \quad \rho_-(n) = -\frac{a_2(n)}{3} - \frac{\sqrt{a_2^2(n) - 3a_1(n)}}{3}. \]

Moreover, a direct computation shows that

\[ a_2^2(n) - 3a_1(n) = \alpha^2 b^2 d^2 \omega^4 n^4 + \alpha \omega^2 (3(b+d) - 2(\alpha + \gamma)) n^2 + c^2 \alpha^2 - c \alpha \gamma + \gamma^2 > 0, \]

for example in the case \( \omega^2 > \frac{2(\alpha + c)}{b + d} := \omega_1^2(a, b, c, d) \), since for any \( c, \alpha, \) and \( \gamma \) we have that

\[ c^2 \alpha^2 - c \alpha \gamma + \gamma^2 > 0. \]

In other words, for \( |\omega| > \omega_0 \), we have that \( \rho_\pm(n) \) is real for any \( n \in \mathbb{Z} \). Hereafter, we choose appropriately \( |\omega| > \omega_0 \) and \( a, b, c, d \) to guarantee that \( a_1(n) < 0 \) for \( n \in \mathbb{Z} \setminus \{0\} \), meaning that \( \rho_+(n) > 0 > \rho_-(n) \) for \( n \in \mathbb{Z} \setminus \{0\} \). So, for \( n \in \mathbb{Z} \setminus \{0\} \), the polynomial \( p_n \) has either two positive real roots \( \lambda_2(n), \lambda_3(n) \) or two complex conjugate root \( \lambda_2(n), \lambda_3(n) \in \mathbb{C} \setminus i\mathbb{R} \) with \( \lambda_3(n) = \overline{\lambda_2(n)} \) and \( \Re(\lambda_2(n)) > 0 \).

Under previous assumptions, we are able to describe the form of the eigenvalues for \( \widetilde{A}(n) \) for \( n \neq 0 \). In this case, we have that

\[ \beta_3(n) = -\beta_4(n) = \sqrt{\lambda_2(n)} \in \mathbb{C} \setminus i\mathbb{R}, \quad \beta_5(n) = -\beta_6(n) = \sqrt{\lambda_3(n)} \in \mathbb{C} \setminus i\mathbb{R}, \]

where \( \lambda_2(n) \in \mathbb{C} \setminus i\mathbb{R} \) with \( \Im(\lambda_2(n)) \geq 0 \). A direct computation shows that \( \beta_m(n) \) for \( 1 \leq m \leq 6 \) is a single eigenvalue with right eigenvector

\[ v_m(n) = (in, \beta_m(n), \beta_m^2(n), \beta_m^3(n), inQ(\beta_m(n), n), in\beta_m(n)Q(\beta_m(n), n))^t, \]
where
\[ Q(\beta_m(n), n) = \frac{\Lambda_m(n)}{\Theta_m(n)}, \quad \Theta_m(n) = \beta_m^2(n) - (c\alpha + n^2), \]
\[ \Lambda_m(n) = \omega c\alpha (b \beta_m^2(n) - (bn^2 + 1)). \]

It is also straightforward to show that left eigenvector \( z_m(n) \) is given by
\[ z_m(n) = Q(m, n) \left( \frac{\beta_m^3(n)}{i n}, \frac{\beta_m^2(n)}{i n}, \frac{-i n \omega \beta_m(n) (\gamma - \alpha d)}{\Theta_m(n)}, \frac{-i n \omega (\gamma - \alpha d)}{\Theta_m(n)} \right), \]
where \( Q(m, n) \) is taken such that
\[ z_m(n) v_l(n) = \delta_l^m. \]

If we introduce the matrices \( Z(n) \) and \( V(n) \) given by
\[
Z(n) = \begin{pmatrix}
z_1(n) \\
z_2(n) \\
z_3(n) \\
z_4(n) \\
z_5(n) \\
z_6(n)
\end{pmatrix}, \quad V(n) = (v_1(n), v_2(n), v_3(n), v_4(n), v_5(n), v_6(n)),
\]
we have \( Z(n) \cdot V(n) = I_6 \) and
\[ Z(n) \tilde{A}(k) V(k) = \text{diag}(\beta_1(n), \beta_2(n), \beta_3(n), \beta_4(n), \beta_5(n), \beta_6(n)), \quad n \in \mathbb{Z}. \]

Now, we observe that given any vector \( \tilde{U}(n) \in \mathbb{R}^6 \), we may write
\[ \tilde{U}(n) = V(n) \cdot Z(n) \tilde{U}(n) = V(n) U^\#(n), \]
where the vector \( U^\#(n) \) is defined as
\[
U^\#(n) = Z(n) \tilde{U}(n) = \begin{pmatrix}
U^\#_1(n) \\
U^\#_2(n) \\
U^\#_3(n) \\
U^\#_4(n) \\
U^\#_5(n) \\
U^\#_6(n)
\end{pmatrix}.
\]

Using this representation, we have for \( U = \sum_{n \in \mathbb{Z}} \tilde{U}(n) e^{inx} \) that
\[
U = \sum_{n \in \mathbb{Z}} \sum_{m=1}^6 v_m(n) U^\#_m(k) e^{inx}, \quad AU = \sum_{n \in \mathbb{Z}} \sum_{m=1}^6 \beta_m(n) v_m(n) U^\#_m(n) e^{inx}. \quad (2.5)
\]
We define the projections $\pi_0$ and $\pi_1$ by
\[
\pi_0 U = \sum_{n \in \mathbb{Z}} \sum_{m=1}^{2} v_m(n) U_m^\#(k) e^{inx},
\]
\[
\pi_1 U = \sum_{n \in \mathbb{Z}} \sum_{m=4}^{6} v_m(n) U_m^\#(k) e^{inx}.
\]

Moreover, the roots of the polynomial $p_n$ defined in (2.4) are explicitly given by
\[
\lambda_1 = -\frac{1}{3} a_2(n) + (S(n) + T(n)),
\]
\[
\lambda_2 = -\frac{1}{3} a_2(n) - \frac{1}{2} (S(n) + T(n)) + \frac{i\sqrt{3}}{2} (S(n) - T(n)),
\]
\[
\lambda_3 = -\frac{1}{3} a_2(n) - \frac{1}{2} (S(n) + T(n)) - \frac{i\sqrt{3}}{2} (S(n) - T(n)),
\]
where $S(n)$ and $R(n)$ are numbers defined as
\[
S(n) = 3\sqrt{R(n) + \sqrt{D(n)}}, \quad T(n) = 3\sqrt{R(n) - \sqrt{D(n)}},
\]
where the discriminant $D(n)$ of $p_n$ is defined as
\[
D(n) = Q^3(n) + R^2(n),
\]
with $Q$ and $R$ given by
\[
Q(n) = \frac{3a_1(n) - a_2^2(n)}{9},
\]
\[
R(n) = \frac{9a_1(n)a_2(n) - 27a_0(n) - 2a_3^2(n)}{54}.
\]

We also have that $S(n) + T(n) \in \mathbb{R}$ and that $S(n) - T(n) \in \mathbb{R}$ for $D(n) \geq 0$, and $S(n) + T(n) \in \mathbb{R}$ and that $S(n) - T(n) \in i\mathbb{R}$ for $D(n) < 0$. Then, from this formulas we conclude for $|n|$ large enough that
\[
|\sqrt{D(n)}| \simeq O(n^6), \quad |R(n)| \simeq O(n^6),
\]
implying that
\[
|T(n)| \simeq O(n^2), \quad |S(n)| \simeq O(n^2), \quad |\lambda_m(n)| \simeq O(n^2),
\]
and so, for $|n|$ large enough and $1 \leq m \leq 6$, we have that
\[
|\beta_m(n)| \simeq O(|n|).
Using this fact it is not difficult to verify that in terms of the coefficient vectors $U^\#(n)$ we have the following equivalence of norms:

$$\|U\|_H^2 \sim \sum_{n \in \mathbb{Z}} (1 + n^2)^2 |U^\#(n)|^2, \quad \|U\|_X^2 \sim \sum_{n \in \mathbb{Z}} (1 + n^2)^3 |U^\#(n)|^2. \quad (2.8)$$

From the equivalences in (2.8) it is evident that $\pi_0$ and $\pi_1$ are bounded on $H$ and on $X$ with $\pi_0 + \pi_1 = I$, and it is clear that $AX_j \subset H_j$ where $X_j = \pi_j X$ and $H_j = \pi_j H$ for $j = 0, 1$. This yields the spectral decompositions $H = H_0 \oplus H_1$ and $X = X_0 \oplus X_1$.

### 2.4 Linear dynamics analysis - Hypotheses (H0) and (H1).

In this subsection, we want to establish the conditions hypotheses (H0) and (H1) in [1], under which we are able to solve the uncoupled system to the linear level in the spaces $H_0$ and $H_1$. First we consider the center subspace $H_0$. We define the bounded $C^0$-group $\{S_0(t)\}_{t \in \mathbb{R}}$ on $H_0$ with infinitesimal generator $A_0 = A|_{X_0}$ by

$$S_0(t)U = \sum_{n \in \mathbb{Z}} \sum_{m=1}^2 \nu_m(n) U^\#_m(n) e^{\beta_m(n) y} e^{inx}.$$

It is straightforward to see that the group $\{S_0(t)\}_{t \in \mathbb{R}}$ satisfies:

[H0] $A_0$ is the generator of a $C^0$-group $\{S_0(t)\}_{t \in \mathbb{R}}$ on $H_0$ with subexponential growth. I.e., given any $\beta > 0$, there is a constant $M > 0$ such that

$$\|S_0(t)\|_{\mathcal{L}(H_0)} \leq M e^{\beta |t|} \quad \text{for all } t \in \mathbb{R}.$$

Now, we consider the inhomogeneous linear equation in the hyperbolic subspace $H_1$,

$$\frac{d}{dy}U(y) = A_1 U(y) + G(y), \quad (2.9)$$

where $A_1 = A|_{X_1}$. We need to observe that $|\Re(\beta_m(n))| \geq \varepsilon > 0$ for all $n \in \mathbb{Z}$ and $m = 3, 4, 5, 6$ when $n \neq 0$. In fact, assume that $\rho = \nu + i\beta$ is a root of the polynomial $p_n$ with $\nu > 0$ (a direct computation shows that $\nu \neq 0$). So, we have that $p_n$ is divided by the quadratic polynomial

$$q(\lambda) = (\lambda - \rho)(\lambda - \bar{\rho}) = z^2 - 2\nu \lambda + |\rho|^2,$$

which implies that the residue $r(\lambda)$ must be zero, meaning that

$$a_1(n) - |\rho|^2 + a_2(n) + 2\nu = 0, \quad a_0(n) - |\rho|^2(a_2(n) + 2\nu) = 0.$$
So, if we assume that \(a_1(n) + a_2(n) < 0\) (which holds for large \(n\)), then we have that
\[
2\nu = -a_1(n) - a_2(n) + |\rho|^2 \geq |\rho|^2.
\]
We note that condition \(a_1(n) + a_2(n) < 0\) holds, whenever
\[
\omega^2 > \frac{2(a + c)}{b + d} := \omega_2(a, b, c, d).
\]
Now, from the Cauchy lower bounds for roots of monic polynomials (see [4]), we have for any root \(\lambda_m(n)\) of \(p_n\) that
\[
|\lambda_m(n)| \geq \frac{|a_0(n)|}{\max\{1, |a_0(n)| + |a_1(n)|, |a_0(n)| + |a_2(n)|\}} \geq \frac{|a_0(n)|}{1 + 2|a_0(n)| + |a_1(n)| + |a_2(n)|},
\]
which implies that there exists \(\varepsilon > 0\) such that for any \(|n| \geq 1\), \(|\lambda_m(n)|^2 > 2\varepsilon^2\).
In other words, we have for \(m = 3, 5\) that,
\[
\Re(\lambda_m(n)) \geq \frac{|\lambda_m(n)|^2}{2} > \varepsilon^2.
\]
From these facts, we conclude for \(m = 3, 5\) and \(|n| \geq 1\) that
\[
(\Re(\beta_m(n)))^2 \geq \Re(\beta_m^2(n)) \geq \frac{|\lambda_m(n)|^2}{2} > \varepsilon^2
\Leftrightarrow |\Re(\beta_m(n))| > \varepsilon.
\]
So, for any \(|n| \geq 1\) and \(m = 3, 4, 5, 6\), we have that \(|\Re(\beta_m(n))| > \varepsilon\).

Hereafter we will assume \(m = 3, 4, 5, 6\) and \(0 \leq \varrho < \varepsilon\). If we suppose \(U \in C^1(\mathbb{R}, H_1) \cap C(\mathbb{R}, X_1)\) is a solution belonging to \(H_1^0\) and \(G \in C(\mathbb{R}, X_1) \cap H_1^0\), where
\[
Y^\varrho := \{u \in C(\mathbb{R}, Y) : ||u||_{Y^\varrho} := \sup_t e^{-\varrho|t|}||u(t)||_Y < \infty\}. \quad (2.10)
\]
Now, using the Fourier series expansion in \(x\) and multiplying by the matrix \(Z(n)\) yields the differential equation
\[
\frac{d}{dy} U^\#_m(n, y) = \beta_m(n) U^\#_m(n, y) + G^\#_m(n, y).
\]
The functions \(G^\#_m(n, \cdot)\) and \(U^\#_m(n, \cdot)\) belong to \(\mathbb{R}^e (Y = \mathbb{R}\) in (2.10)). From the fact that \(|\Re(\beta_m(n))| > \varepsilon > \varrho\), we conclude necessarily that
\[
U^\#_u(n, y) = \int_{-\infty}^{y} e^{\beta_u(k)(y-\tau)} G^\#_u(n, \tau) d\tau, \quad (2.11)
\]
\[
U^\#_s(n, y) = \int_{-\infty}^{y} e^{\beta_s(n)(y-\tau)} G^\#_s(n, \tau) d\tau. \quad (2.12)
\]
As a direct consequence, any solution of (2.9) in \( H^p \) is unique. We will see that the formulas (2.11)-(2.12) together with the representation for \( U = \pi_1 U \) in (2.7) allow us to establish the existence of a solution in \( H^1_\rho \). To see this, we decompose equation (2.9) using projections into the “unstable” and “stable” subspaces. The projections for \( U \in H \) are

\[
\pi_u U = \sum_{n \in \mathbb{Z}} \sum_{m=3,5} v_m(n) U_m^#(n) e^{inx}, \\
\pi_s U = \sum_{n \in \mathbb{Z}} \sum_{m=4,6} v_m(n) U_m^#(n) e^{inx}.
\]

Clearly \( \pi_u \) and \( \pi_s \) are bounded on \( H \) and \( X \) and \( \pi_u + \pi_s = \pi_1 \). Now, we introduce a Green’s function operator \( S(y) \) defined for nonzero \( y \in \mathbb{R} \) by

\[
S(y)U = \begin{cases} 
-\sum_{n \in \mathbb{Z}} \sum_{m=3,5} v_m(n) U_m^#(n) e^{\beta_m(n)y} e^{inx}, & y < 0, \\
\sum_{n \in \mathbb{Z}} \sum_{m=4,6} v_m(n) U_m^#(n) e^{\beta_m(n)y} e^{inx}, & y > 0.
\end{cases}
\]

By the definition of the norm in \( H \) and \( X \) (see (2.8)), we see directly for \( Y = H \) or \( X \) that,

\[
\| S(y)U \|_H \sim \sum_{n \in \mathbb{Z}} (1 + n^2)^2 (e^{2R(\beta_3(n))y}|U_3(n)|^2 + e^{2R(\beta_5(n))y}|U_5(n)|^2) \leq e^{2\varepsilon} \| U \|_H^2, \quad y < 0
\]

and also that

\[
\| S(y)U \|_H \sim \sum_{n \in \mathbb{Z}} (1 + n^2)^3 (e^{-2R(\beta_3(n))y}|U_3(n)|^2 + e^{-2R(\beta_5(n))y}|U_5(n)|^2) \leq e^{-2\varepsilon y} \| U \|_H^2, \quad y > 0.
\]

Moreover, we already have that

\[
\| S(y)U \|_Y \leq e^{-2\varepsilon |y|} \| U \|_Y^2, \quad Y = H \text{ or } X.
\]

As a consequence of the Mean Value Theorem applied to the \( f(w) = e^{-w} \) with \( w > 0 \), we have that

\[
\left| \frac{e^{-w} - 1}{-w} \right| \leq 1,
\]

which implies for \( t > 0 \) that

\[
\sup_{\lambda \geq \varepsilon} \lambda^{-1} |e^{-\lambda y} - 1| \leq t, \quad \sup_{\lambda \geq \varepsilon} \lambda e^{-\lambda y} = \begin{cases} \varepsilon e^{-\varepsilon y}, & \varepsilon y \geq 1, \\
\frac{1}{ey}, & \varepsilon y \leq 1.
\end{cases}
\]
Following the same type of calculation and using previous facts, one can easily verify that for some constant $C$ (independent of $y$) we have the following norm bounds:

\[
\|S(y)\|_{L(Y)} \leq Ce^{-\varepsilon|y|}, \quad \text{for } Y = H \text{ or } X
\]

\[
\|S(y)\|_{L(H,X)} \leq \begin{cases} 
Ce^{-\varepsilon y}, & \varepsilon|t| \geq 1, \\
C|y|^{-1}, & \varepsilon|y| \leq 1,
\end{cases}
\]

\[
\|S(y) - \pi_s\|_{L(X,H)} + \|S(-y) + \pi_u\|_{L(X,H)} \leq Cy, \quad y > 0,
\]

where $L(Y)$ and $L(H,X)$ respectively denote the space of bounded operators on $Y$, and from $H$ to $X$. Clearly, we have that $S(y) \to \pi_s$ (resp. $-\pi_u$) strongly as $y \to 0^+$ (resp. $0^-$). Therefore the families $\{S(y)\}_{y>0}$ and $\{-S(-y)\}_{y>0}$ are analytic semigroups in $\pi_sH$ and $\pi_uH$ respectively [18, p.62]. Moreover, we also have that $S$ is $C^1$ from $\mathbb{R} \setminus \{0\}$ to $L(H)$ with $dS(y)/dy = A_1S(y)$. Therefore, we conclude that equation (2.11) yield the formula

\[
U(y) = \int_{-\infty}^{\infty} S(y - \tau)G(\tau) \, d\tau
\]

for the solution of (2.9). In order to establish that $U \in C(\mathbb{R},X)$, $U \in H_1^\varrho$, and $dU/dy$ exists in $H$ and satisfies (2.9), we only need to follow the standard computations made in the case of the Benney-Luke equation in [1]. In other words, we have verified that:

[H1] There exists $\varepsilon > 0$ and a positive function $M_1$ on $[0,\varepsilon)$ such that for any $\varrho \in [0,\varepsilon)$ and for any $g_1 \in C(\mathbb{R},X_1) \cap H_1^\varrho$ the equation

\[
\frac{d}{dt} u_1 = A_1u_1 + g_1
\]

has a unique solution in $H_1^\varrho$ given by $u_1 = K_1g_1$, where $K_1 \in L(H_1^\varrho)$ with $\|K_1\|_{L(H_1^\varrho)} \leq M_1(\varrho)$. Furthermore $\|K_1\|_{L(X_1^\varrho)} \leq M_1(\varrho)$.

Under these conditions J. Quintero and R. Pego in [1] showed the existence of a local infinite dimensional center manifold with infinite codimension for

\[
\frac{d}{dy} U(y) = AU(y) + G(y), \quad (2.13)
\]

under the hypotheses that the nonlinearity $G$ has a smoothing property described $G(H) \subset X$. This hypothesis on $G$ is a stronger condition than those imposed in many works related with the existence center manifolds, but this completely natural for the \textit{abcd}-Boussinesq system considered in this paper. It is important to note that the cutoff performed to get the local manifold must be done in the $H$ norm, and not in the $X$ norm. This is important since we need to use an energy functional which is defined on $H$, which is conserved in time for classical solutions (taking values in $X$), but is indefinite in general.
Theorem 2.1 (Local Center Manifold Theorem). Let $H$, $X$, $A$, $\pi_0$, $\pi_1$ and $G$ be as above, and let

$$B(\delta) = \{ y \in H_0 : \|y\|_H < \delta \}.$$ 

Then for all sufficiently small $\delta > 0$ there exists $\phi_\delta : H_0 \to X_1$ such that

(i) $\phi_\delta(0) = 0$ and $D\phi_\delta(0) = 0$.

(ii) $\phi_\delta \in C_b(H_0, X_1) \cap \text{Lip}(H_0, X_1)$, and on any ball $B(\delta')$, $\phi_\delta$ has Lipschitz constant $L(\delta')$ satisfying $L(\delta') < \frac{1}{2}$ and $L(\delta') \to 0$ as $\delta' \to 0^+$.

(iii) The manifold $M_\delta \subset X$ given by

$$M_\delta := \{ \xi + \phi_\delta(\xi) : \xi \in X_0 \}$$

is a local integral manifold for (2.13) over $B(\delta) \cap X_0$. That is, given any $y \in M_\delta$ there is a continuous map $u : \mathbb{R} \to M_\delta$ with $u(0) = y$, such that for any open interval $J$ containing 0 with $\pi_0 u(J) \subset B(\delta)$ it follows that $u$ is a classical solution of (2.13) on $J$. Moreover, $u_0 := \pi_0 u$ is the unique classical solution on $J$ with $u_0(0) = \pi_0 y$ to the reduced equation

$$\frac{d}{dt} u_0(t) = A_0 u_0(t) + F_\delta(u_0(t)), \quad (2.14)$$

where $F_\delta : H_0 \to X_0$ is locally Lipschitz and is given by

$$F_\delta(w) := \pi_0 f(w + \phi_\delta(w)).$$

(iv) For any open interval $J \subset \mathbb{R}$, every classical solution $u_0 \in C^1(J, H_0) \cap C(J, X_0)$ of the reduced equation (2.14) such that $u_0(t) \in B(\delta)$ for all $t \in J$ yields, via $u = u_0 + \phi_\delta(u_0)$, a classical solution $u$ of the full equation (2.13) on $J$.

(v) The manifold $M_\delta$ contains all classical solutions on $\mathbb{R}$ that satisfy for all $t$.

$$\|u(t)\|_H \leq \delta.$$ 

3 Global existence and stability for $|\omega| > 1$ (large enough)

For for $b = d$, $a > d$, we are interested in proving global existence of classical solutions on the local center manifold, for initial data that is small in $H$-norm, which follows from the fact that the zero solution is stable on the
center manifold characterized by the graph of a function \( \phi_{\delta} : H_0 \to X_1 \). We use strongly the existence an energy functional that is conserved in time for classical solutions in the case \( b = d \) and \( a > d \).

**Energy for the abcd-Boussinesq system with** \( b = d \). Recall that we are using the variables

\[
\begin{align*}
&u_1 = \partial_x v, \quad u_2 = \partial_y v, \quad u_3 = \partial_{yy} v, \quad u_4 = \partial_{yyy} v, \quad u_5 = u, \quad u_6 = \partial_y u,
\end{align*}
\]

then we have for \( b = d \) that the travelling wave system takes the form

\[
- \omega u_x + d\omega u_{xxx} + d\omega u_{xyy} + v_{xx} + v_{yy} - cv_{xxxx} - 2cv_{xxyy} - cv_{yyyy} + (uv_x^p)_x + (uv_y^p)_y = 0, \quad (3.1)
\]

\[
\omega v_x - d\omega v_{xxx} - d\omega v_{xyy} - u + au_{xx} + au_{yy} - \frac{1}{p + 1} (v_x^{p+1} + v_y^{p+1}) = 0. \quad (3.2)
\]

Now, if we assume that \( u, v \) are sufficiently smooth, then a direct computation shows that

\[
\begin{align*}
\int_0^{2\pi} \omega v_x u_y \, dx &= \int_0^{2\pi} (\omega \partial_y (v_x u) + \omega v_y u_x) \, dx, \\
\int_0^{2\pi} d\omega v_{xxx} u_y \, dx &= \int_0^{2\pi} (d\omega \partial_y (v_{xxx} u) + d\omega v_y u_{xxx}) \, dx, \\
\int_0^{2\pi} d\omega v_{xyy} u_y \, dx &= \int_0^{2\pi} (d\omega \partial_y (v_{xyy} u) + d\omega v_y u_{xyy}) \, dx, \\
\int_0^{2\pi} ((uv_x^p)_x + (uv_y^p)_y) v_y \, dx &= \\
\int_0^{2\pi} \left( \partial_y (uv_y^{p+1}) - \frac{u}{p + 1} \partial_y (v_x^{p+1} + v_y^{p+1}) \right) \, dx, \\
\int_0^{2\pi} v_{yyyy} v_y \, dx &= \int_0^{2\pi} \left( \partial_y (v_{yyyy} v) - \frac{1}{2} \partial_y (v_y^2) \right) \, dx.
\end{align*}
\]

Multiplying equation (3.1) by \( v_y \), equation (3.2) by \( \partial_y u \), and subtracting them, we have that

\[
\partial_y \left[ \int_0^{2\pi} -|v_x|^2 + |v_y|^2 - c|v_{xx}|^2 + 2c|v_{xy}|^2 + c|v_{yy}|^2 - |u|^2 - a|\partial_x u|^2 + a|u_y|^2 \\
+ 2\omega v_x u - 2d\omega v_{xxx} u - 2d\omega v_{xyy} u - 2cv_{yyyy} v_y + \frac{2}{p + 1} u (pv_{y}^{p+1} - v_x^{p+1}) \, dx \right] = 0.
\]
\[
(3.3)
\]
So, in the variables \( u_1, u_2, u_3, u_4, u_5, u_6 \), we have that there exists an energy functional \( \mathcal{E} : H \to \mathbb{R} \) defined by \( \mathcal{E}(U) = \mathcal{E}_0(U) + \mathcal{E}_1(U) \) which is conserved with respect to \( y \) such that the quadratic part \( \mathcal{E}_0(U) \) is given by

\[
\mathcal{E}_0(U) = \frac{1}{2\pi} \int_0^{2\pi} \left[ -|u_1|^2 + |u_2|^2 - c|\partial_x u_1|^2 + 2c|\partial_x u_2|^2 + c|u_3|^2 - |u_5|^2 - a|\partial_x u_5|^2 \\
+ a|u_6|^2 + 2\omega u_1 u_5 - 2d\omega \partial_x u_2 u_6 \right] dx - \frac{d\omega}{\pi} (\partial_{xx} u_1, u_5)_{-1,1} - \frac{c}{\pi} (u_4, u_2)_{-1,1},
\]

and the nonlinear part \( \mathcal{E}_1 \) is defined by

\[
\mathcal{E}_1(U) = \frac{1}{\pi(p+1)} \int_0^{2\pi} u_5 (p u_2^{p+1} - u_1^{p+1}) dx,
\]

where \( (\cdot, \cdot)_{-1,1} \) represents the pairing between \( \tilde{H}^{-1} \) and \( \tilde{H}^1 \). From the definition, \( \mathcal{E} \) is a smooth function from \( H \) to \( \mathbb{R} \). After multiplying appropriately the equation (2.1) by \( u_2 \) and equation (2.2) by \( u_6 \), one can easily verify that if \( U \in C^1(\mathbb{R}, H) \) is a classical solution of the first order equation (2.3), then for all \( y \in \mathbb{R} \)

\[
\frac{d}{dy} \mathcal{E}(U(y)) = 0.
\]

Even though we have the conservation of the energy \( \mathcal{E} \), we can not use this to obtain a solution by the variational method since neither \( \mathcal{E} \) nor \( \mathcal{E}_0 \) is non negative defined in the space \( H \). However, we will see that energy \( \mathcal{E}_0 \) is non negative on the center space \( H_0 \), and also that this controls the norm of \( U \) in \( H \), via the center manifold result. From the definition of the variable \( U = (u_1, u_2, u_3, u_4, u_5, u_6) \), we have a priori that \( u_1 = \partial_x v \) has mean zero on \([0, 2\pi]\), meaning that \( \hat{U}_1(0) = 0 \).

**Lemma 3.1.** Let \( |\omega| \geq \max\{\omega_0, \omega_1, \omega_2\} \) and \( a > d \). Then there is a positive constant \( M_0 > 1 \) such that for any \( U \in H_0 \) with \( \hat{U}_1(0) = 0 \),

\[
M_0^{-1} \|U\|_H^2 \leq \mathcal{E}_0(U) \leq M_0 \|U\|_H^2.
\]

**Proof.** From the Fourier series representation of \( U \in H_0 \) given with \( \hat{U}_1(0) = 0 \), we have that

\[
U = \begin{pmatrix} 0 \\ U_2^\#(0) \end{pmatrix} + \sum_{|n| > 1} \begin{pmatrix} in(U_1^\#(n) + U_2^\#(n)) \\ \beta_1(n)(U_1^\#(n) - U_2^\#(n)) \\ \beta_2^2(n)(U_1^\#(n) + U_2^\#(n)) \\ \beta_3^3(n)(U_1^\#(n) - U_2^\#(n)) \\ inQ_1(\beta_1(n), n)(U_1^\#(n) + U_2^\#(n)) \\ in\beta_1(n)Q_1(\beta_1(n), n)(U_1^\#(n) - U_2^\#(n)) \end{pmatrix} e^{inx}
\]

\[
= \hat{U}(0) + \sum_{|n| > 1} \hat{U}(n)e^{inx}.
\]
We also have that $\mathcal{E}_0(U) = \sum_{n \in \mathbb{Z}} \mathcal{E}_0 \left( \hat{U}(n)e^{inx} \right)$. We note that

$$\mathcal{E}_0(\hat{U}(0)) = |U_2^-(0)|^2,$$

On the other hand, for $\beta_1(n) = \beta$ we have that

$$\mathcal{E}_0 \left( \hat{U}(n)e^{inx} \right) = \Gamma_1(n) |U_1^+(n) + U_2^-(n)|^2 + \Gamma_2(n) |U_1^+(n) - U_2^-(n)|^2,$$

where

$$\Gamma_1(n) = -n^2 - cn^4 + c\beta^4 - n^2(1 + an^2)Q^2(\beta, n) + 2\omega n^2(1 + dn^2)Q(\beta, n),$$

$$\Gamma_2(n) = |\beta|^2 \left( 1 + n^2 \left( 2c + aQ^2(\beta, n) + 2dnQ(\beta, n) \right) - 2c\beta^2 \right).$$

Recall that we have that $\beta_1^2(n) = \lambda_1(n) < 0$ for $|n| > 0$, so we conclude that $Q(\beta, n) > 0$ for $|n| > 0$. Thus, we have the right side of the second term $\Gamma_2$ is positive. Now, for the first term note that

$$-n^2 - cn^4 + c\beta^4 - n^2(1 + an^2)Q^2(\beta, n) + 2\omega n^2(1 + dn^2)Q(\beta, n) = \frac{L_1 + L_2}{\Theta_1^2(n)},$$

where $L_1$ and $L_2$ are given by

$$L_1 = (c\beta^4 - n^2(1 + cn^2)) \Theta_1^2(n),$$

$$L_2 = 2\omega n^2 \left( 1 + dn^2 \right) \Lambda_1(n) \Theta_1(n) - n^2 \Lambda_1^2(n)(1 + an^2).$$

Then we have that

$$L_1 + L_2 = c\beta^4 + \vartheta_3(n)\beta^6 + \vartheta_2(n)\beta^4 + \vartheta_1(n)\beta^2 + \vartheta_0(n),$$

with

$$\vartheta_3(n) = -2c(\alpha a + n^2),$$

$$\vartheta_2(n) = c(\alpha a + n^2)^2 + \left[ c(\omega^2d^2 - 1)n^2 + \omega^2cad(1 - cad) + (\omega^2cad - 1) \right] n^2,$$

$$\vartheta_1(n) = -2 \left[ c(\omega^2d^2 - 1)n^4 + \left( (\omega^2cad - 1) + \alpha a(\omega^2d - c) + \alpha(\omega^2 - 1) \right) \right] n^2,$$

$$\vartheta_0(n) = \left[ c(\omega^2d^2 - 1)n^4 + \left( (\omega^2cad - 1) + \alpha a(\omega^2d - c) + \alpha(\omega^2 - 1) \right) \times \right. \times (\alpha a + n^2)n^2.\$$

Note that $\vartheta_3(n) \leq 0$. Now, using that $\omega^2 \geq \max\{1, \frac{\epsilon}{b}, \frac{\epsilon^2}{b}, \frac{\epsilon}{b} \}$, $\alpha a = 1$, $b = d$ and $a > d$, we see that

$$\vartheta_2(n) \geq 0, \quad \vartheta_1(n) \leq 0, \quad \vartheta_0(n) \geq 0.$$

Then using that $\beta_1^2(n) < 0$ for $|n| > 0$, we finally get that

$$L_1 + L_2 \geq 0.$$
This fact implies that
\[
\min_{|n| > 0}(\Gamma_1(n), \Gamma_2(n))(|U_1^+(n) + U_2^+(n)|^2 + |U_1^+(n) - U_2^+(n)|^2) \leq \mathcal{E}_0\left(\bar{U}(n)e^{inx}\right)
\]
\[
\leq \max_{|n| > 0}(\Gamma_1(n), \Gamma_2(n))(|U_1^+(n) + U_2^+(n)|^2 + |U_1^+(n) - U_2^+(n)|^2),
\]
which implies that
\[
\min_{|n| > 0}(\Gamma_1(n), \Gamma_2(n))(|U_1^+(n)|^2 + |U_2^+(n)|^2)
\]
\[
\leq \mathcal{E}_0\left(\bar{U}(n)e^{inx}\right) \leq \max_{|n| > 0}(\Gamma_1(n), \Gamma_2(n))(|U_1^+(n)|^2 + |U_2^+(n)|^2).
\]

In other words, we have shown that
\[
\mathcal{E}(U) \sim \sum_{n \in \mathbb{Z}} (1 + n^2)^2 \left(|U_1^+(n)|^2 + |U_2^+(n)|^2\right) \sim \|U\|_H^2.
\]

The first consequence of this fact is the following result:

**Corollary 3.1.** Let $|\omega| \geq \max\{\omega_0, \omega_1, \omega_2\}$ and $a > d$. Then there are $\delta_1 > 0$ and $M_1 > 1$ such that for any $U \in H_0$ with $\tilde{U}(0) = 0$ and $\|U\|_H < \delta_1$,
\[
\frac{1}{M_1}\|U\|_H^2 \leq |\mathcal{E}(U)| \leq M_1\|U\|_H^2.
\]

**Proof.** First note that from the Sobolev inequality, there is some positive constant $C = C(p)$ (independent of $U$) such that
\[
|\mathcal{E}_1(U)| = \left|\frac{1}{\pi(p+1)} \int_0^{2\pi} u_5(pu_2^{p+1} - u_1^{p+1}) dx\right|
\]
\[
\leq C\|u_5\|_{H^1}\left(\|u_2\|_{H^1}^{p+1} + \|u_1\|_{H^1}^{p+1}\right)
\]
\[
\leq C\|U\|_{H}^{p+2}.
\]
Moreover for some constants $C_0$ and $C_1 = C_1(p)$ (independent of $U$), we conclude that
\[
|\mathcal{E}(U)| \geq |\mathcal{E}_0(U)| - |\mathcal{E}_1(U)|
\]
\[
\geq C_0\|U\|_H^2 - C_1\|U\|_H^{p+2}
\]
\[
\geq \|U\|_H^2 (C_0 - C_1\|U\|_H^p).
\]
Let $\delta_1 > 0$ be taken such that $C_0 - \delta_1^pC_1 > 0$. Then, for $\|U\|_H \leq \delta_1$ with $U \in H_0 \setminus \{0\}$, we have that
\[
|\mathcal{E}(U)| \geq \|U\|_H^2 (C_0 - C_1\delta_1^p).
\]
The second claim of this lemma follows directly. In fact, for \( U \in H \) we have that
\[
|\mathcal{E}(U)| \leq C (\|U\|_{H}^{2} + \|U\|_{H}^{p+2}) \\
\leq C\|U\|_{H}^{2} (1 + \|U\|_{H}^{p}).
\]

Now, we are interested in estimating the energy \( \mathcal{E} \) on the center manifold. In other words, we want to obtain a similar estimates for the lift of \( \mathcal{E} \) to the center manifold \( M_{\delta} \).

**Lemma 3.2.** Let \( |\omega| \geq \max\{\omega_{0}, \omega_{1}, \omega_{2}\} \) and \( a > d \), and let \( \phi_{\delta} \) as in Theorem 2.1. Then there exist constants \( \delta_{2} > 0 \) and \( C_{2} > 1 \) such that for all \( \xi \in H_{0} \) with \( \|\xi\|_{H} < \delta_{2} \) we have
\[
\frac{1}{C_{2}}\|\xi\|_{H}^{2} \leq \mathcal{E}(\xi + \phi_{\delta}(\xi)) \leq C_{2}\|\xi\|_{H}^{2}.
\]

**Proof.** Let us define the functional \( \tilde{\mathcal{E}} : H_{0} \rightarrow \mathbb{R} \) by
\[
\tilde{\mathcal{E}}(\xi) := \mathcal{E}(\xi + \phi_{\delta}(\xi)),
\]
where the function \( \phi_{\delta} \) is defined in Theorem 2.1. First note that \( \|\phi_{\delta}(\xi)\|_{H} = o(\|\xi\|_{H}) \). Since \( \mathcal{E} \) is smooth and \( \mathcal{E}(0) = 0 \), then \( \mathcal{E}'(\xi) = O(\|\xi\|_{H}) \). As a consequence of this fact and that \( \mathcal{E}_{1}(U) = O(\|U\|_{H}^{p+2}) \), we have for \( \xi \in H_{0} \) that
\[
\mathcal{E}(\xi + \phi_{\delta}(\xi)) = \mathcal{E}_{0}(\xi) + O(\|\xi\|_{H}\|\phi_{\delta}(\xi)\|_{H}) + \mathcal{E}_{1}(\xi + \phi_{\delta}(\xi))
\]
\[
= \mathcal{E}_{0}(\xi) + o(\|\xi\|_{H}^{2}).
\]
as \( \|\xi\|_{H} \rightarrow 0 \). Then by the previous result, we get the conclusion.

We first establish that solutions starting in the center manifold are appropriately bounded.

**Lemma 3.3.** Let \( |\omega| \geq \max\{\omega_{0}, \omega_{1}, \omega_{2}\} \) and \( a > d \), and let \( \phi_{\delta} \) as in Theorem 2.1. If \( \xi \in X_{0} \) be such that \( \hat{\xi}_{1}(0) = 0 \) and that \( \|\xi\|_{X} \leq \delta_{2} \). There exists a unique classical solution \( U(\xi, \cdot) \) for the full problem (without cutoff) (2.3) on \( \mathbb{R} \) with initial condition \( \pi_{0} \circ U(\xi, 0) = \xi \) such that on any open interval \( J \) containing 0,
\[
\|U_{0}(\xi, y)\|_{H} \leq C_{2}\|\xi\|_{H} \text{ for any } y \in J.
\]

**Proof.** We may assume that \( \delta_{2} \) small enough such that \( \delta_{2} << \delta \). Let \( \xi \in X_{0} \) be such that \( \|\xi\|_{X} \leq \delta_{2} \). Now, from Theorem 2.1, there exists a unique continuous function \( U \) from \( \mathbb{R} \) to the local center manifold \( M_{\delta} \) such
that \( \pi_0(U(0)) = \xi \), which turns out to be a classical solution of the equation (2.3) on any open interval \( J \subset \mathbb{R} \) containing 0 such that \( \| \pi_0(U(y)) \|_H \leq \delta \) for any \( y \in J \). On the other hand, since \( U \) is a classical solution and the energy \( E \) is conserved, then we have for any \( y \in J \) that

\[
\frac{1}{C^2} \| \pi_0(U(y)) \|^2_H \leq \mathcal{E}(\pi_0(U(y))) = \mathcal{E}(U(0)) \leq C^2 \| \xi \|^2_H,
\]

meaning \( \| \pi_0(U(y)) \|_H \leq C^2 \| \xi \|_H \), for any \( y \in J \) as desired. A continuation argument shows that \( U \) is a classical solution for the full problem (without cutoff) (2.3) on \( \mathbb{R} \).

Now we are in position to state the main result on the existence and the stability on the center manifold. The proof of this result follows in the same fashion as the result for the Benney-Luke equation done by J. Quintero and R. Pego in [1].

**Theorem 3.1. (Global Existence and stability on the center manifold)** Let \( |\omega| \geq \max\{\omega_0, \omega_1, \omega_2\} \) and \( a > d \), and let \( \phi_{\delta} \) be given by applying Theorem 2.1 to (2.3). There exist positive constants \( \delta_3 \) and \( C_3 \) such that, for any \( \xi \in X_0 \) with \( \tilde{\xi}_1(0) = 0 \) and \( \| \xi \|_H \leq \delta_3 \), there is a unique classical solution \( U \) on \( \mathbb{R} \) to (2.3) such that \( \pi_0(U(0)) = \xi \) and \( \| U(y) \|_H \leq 2C_2 \| \xi \|_H \) for all \( y \in \mathbb{R} \). Moreover, for any \( T > 0 \) the map taking \( \xi \) to \( U \) is Lipschitz continuous from \( H_0 \) to \( C([-T,T],H) \).

### 4 Parametrization and evolution on the center manifold

In this section we assume that \( |\omega| \geq \max\{\omega_0, \omega_1, \omega_2\} \) and \( a > d \). We will see that any global solutions \( U \) on the center manifold is characterized by the initial data in the first two components. This can be accomplished by showing an appropriate correspondence between the first two components and the center-subspace projection \( \pi_0U(0) \). Hereafter, we denote the restriction of any \( U = (u_1, u_2, u_3, u_4, u_5, u_6)^T \) on the first two components by

\[
\mathcal{R}U = (u_1, u_2).
\]

**Lemma 4.1.** The map \( \mathcal{R} \) yields simultaneous isomorphisms \( H_0 \cong \tilde{H}^1 \times \tilde{H}^1 \) and \( X_0 \cong \tilde{H}^2 \times \tilde{H}^2 \).

**Proof.** Given any \( U = \pi_0U \) in \( H_0 \) or \( X_0 \), we use the representation (2.6) to write

\[
\mathcal{R}U = \sum_{n \in \mathbb{Z}} \tilde{V}(n) \begin{pmatrix} U_1^*(n) \\ U_2^*(n) \end{pmatrix} e^{inx},
\]
where
\[ \tilde{V}(0) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \tilde{V}(n) = \begin{pmatrix} in & in \\ \lambda_1(n) & -\lambda_1(n) \end{pmatrix} \]
for \( n \neq 0 \). Since \( |\lambda_1(n)| \) grows asymptotically linearly in \( n \), it follows that
\[ |\tilde{R}\tilde{U}(n)|^2 \leq C(1 + n^2)(|U_1^\#(n)|^2 + |U_2^\#(n)|^2 + |U_3^\#(n)|^2). \]
From the equivalences (2.8) it follows that \( R \) is bounded from \( H_0 \) to \( \tilde{H}^1 \times \tilde{H}^1 \) and from \( X_0 \) to \( \tilde{H}^2 \times \tilde{H}^2 \). Moreover, \( R \) is one-to-one, since if \( RU = 0 \) then \( \tilde{U}(n) = 0 \) for all \( n \) since the matrix \( \tilde{V}(n) \) is invertible.

To see that \( R \) yields an isomorphism, we observe that its inverse is given by the prolongation formula \( U = Pw \). More concretely, given \( w \in \tilde{H}^1 \times \tilde{H}^1 \) or \( \tilde{H}^2 \times \tilde{H}^2 \), we define \( U_1^\#(n) \) and \( U_2^\#(n) \) by
\[ \begin{pmatrix} U_1^\#(n) \\ U_2^\#(n) \end{pmatrix} = \tilde{V}(n)^{-1}\hat{w}(n) = \frac{1}{2in\lambda_1(n)} \begin{pmatrix} \lambda_1(n) & in \\ \lambda_1(n) & -in \end{pmatrix} \begin{pmatrix} \hat{w}_1(n) \\ \hat{w}_2(n) \end{pmatrix}. \]
Then we define \( Pw \) as
\[ Pw = \sum_{n \in \mathbb{Z}} \sum_{m=1}^{2} v_m(n)U_m^\#(n)e^{inx}. \]
So, we have that \( P \) is the inverse of \( R \), and also using (2.8) we see that \( P \) is bounded from \( \tilde{H}^1 \times \tilde{H}^1 \) to \( H_0 \) and from \( \tilde{H}^2 \times \tilde{H}^2 \) to \( X_0 \); since for \( n \neq 0 \), we have that
\[ |U_1^\#(n)|^2 + |U_2^\#(n)|^2 = |\tilde{V}(n)^{-1}\hat{w}(n)|^2 \leq \frac{C}{1 + n^2}|\hat{w}(n)|^2. \]
We also have that \( U = \pi_0U \) and that \( RoP = I_W \), where \( W \) is either \( \tilde{H}^1 \times \tilde{H}^1 \) or \( \tilde{H}^2 \times \tilde{H}^2 \), and also that \( P\circ R = I_W \), where \( W \) is either \( H_0 \) or \( X_0 \).

Due to the the parametrization on the center manifold, we see, using the same arguments as J. Quintero and R. Pego in [1], that

**Theorem 4.1.** Let \( \phi_\delta \) be given by applying Theorem 2.1 to (2.3). There exist positive constants \( \delta_3 \) and \( C_3 \) with the following property. For any \( w = (w_1, w_2) \in \tilde{H}^1 \times \tilde{H}^1 \) such that \( \|w\|_{H^1 \times \tilde{H}^1} < \delta_3 \), there exists a unique \( \xi \in H_0 \) such that \( \|\xi\|_H \leq C_3\|w\|_{H^1 \times \tilde{H}^1} \) and
\[ w = R(\xi + \phi_\delta(\xi)). \]
The map \( w \to \xi \) is Lipschitz continuous, and if \( w \in \tilde{H}^2 \times \tilde{H}^2 \) then \( \xi \in X_0 \).

Now we are in position to establish the main result related with the dynamics on the center manifold.
Theorem 4.2. (Traveling wave solutions via dynamics in $y$) There are positive constants $\delta_1$ and $C_1$ with the following property: Given any initial conditions of the form

$$\left(u_1(0), u_2(0)\right) = (w_1, w_2)$$

in $\tilde{H}^2 \times \tilde{H}^2$ such that $\|(w_1, w_2)\|_{\tilde{H}^1 \times \tilde{H}^1} \leq \delta_1$, equation (2.3) has a unique global classical solution $U \in C^1(\mathbb{R}, H) \cap C(\mathbb{R}, X)$ such that $\|U(y)\|_H \leq C_1 \delta_1$ for all $y \in \mathbb{R}$. The map taking initial conditions to the solution is Lipschitz continuous from $\tilde{H}^1 \times \tilde{H}^1$ to $C([-T, T], H)$, for any $T > 0$.

Moreover, the first two components of the solution satisfy a dispersive, non-linear, nonlocal wave equation of the form

$$\frac{d}{dy} \left( \begin{array}{c} u_1 \\ u_2 \end{array} \right) = \left( \begin{array}{cc} 0 & \partial_x \\ S\partial_x & 0 \end{array} \right) \left( \begin{array}{c} u_1 \\ u_2 \end{array} \right) + \left( \begin{array}{c} 0 \\ g(u_1, u_2) \end{array} \right), \quad (4.2)$$

in which the map $g: \tilde{H}^1 \times \tilde{H}^1 \to \tilde{H}^1$ is Lipschitz with $g(0) = 0$, $Dg(0, 0) = 0$, and where the nonlocal linear operator $S$ defined by equation (4.3).

Proof. The parts of the Theorem referring to existence, uniqueness, stability, and Lipschitz dependence on initial data follow directly from Theorems 3.1 and 4.1. It remains to verify that the first two components $w = RU$ of a solution as given by these results satisfy an equation of the form (4.2). For each $y \in \mathbb{R}$, we set $\xi(y)$ to be determined from $w(y)$ by Theorem 4.1, meaning that

$$w(y) = R(\xi(y)) + R(\phi_\delta(\xi(y))), \quad y \in \mathbb{R}.$$ 

On the other hand, the projection $\pi_0$ on the center space $H_0$ commutes with restriction $R$, implying that

$$\pi_0 w(y) = \mathcal{R} (\xi(y)).$$

but we also have that

$$\pi_0 w(y) = \pi_0 (U(y)) = \pi_0 (U_0(y) + \phi_\delta(U_0(y))) = \pi_0 (U_0(y)),$$

where $U_0$ is the solution on the center space. From this facts, we conclude that $\xi(y) = U_0(y)$. Then using that $\mathcal{P}R\xi = \xi$ and setting $\varphi(w) = (I - \mathcal{P}R)\phi_\delta(\xi)$, we have that

$$U(y) = \xi(y) + \phi_\delta(\xi(y))$$

$$= \xi(y) + \mathcal{P}R(\phi_\delta(\xi(y))) + (I - \mathcal{P}R)(\phi_\delta(\xi(y)))$$

$$= \mathcal{P}(R(\xi(y) + \phi_\delta(\xi(y)))) + (I - \mathcal{P}R)(\phi_\delta(\xi(y)))$$

$$= \mathcal{P} w(y) + \varphi(w(y)).$$
Now, we need to recall that $\phi_8$ maps $X_0$ into $X_1$, so $\varphi(w)$ need not be zero, however the first two components $\mathcal{R}_\varphi(w)$ are zero. On the other hand, $U$ is a classical solution of (2.3), then we have that

$$\frac{d}{dy} w = \mathcal{R}(AU + G(U)) = A(Pw + \varphi(w)) = Aw + \begin{pmatrix} 0 \\ \varphi_3(w) \end{pmatrix}$$

since we have that the first two components $\mathcal{R}_G(U) = 0$ and that $\varphi(w)$ has the first two components zero. We only need to determine the action of the operator $A = \mathcal{R}_A P$. To do this, we use the Fourier transform representation from (2.5) and (4.1). We find that

$$Aw = \sum_{n \in \mathbb{Z}} \begin{pmatrix} \beta_1(n) & -i\beta_1(n) \\ \beta_2(n) & i\beta_2(n) \end{pmatrix} \begin{pmatrix} U^{\#}_1(n) \\ U^{\#}_2(n) \end{pmatrix} e^{inx}$$

$$= \sum_{n \in \mathbb{Z}} \begin{pmatrix} in\beta_1(n) & -in\beta_1(n) \\ \beta_2(n) & i\beta_2(n) \end{pmatrix} \tilde{V}(n)^{-1} \tilde{w}(n) e^{inx}$$

$$= \sum_{n \neq 0} \begin{pmatrix} 0 & in \\ \beta_2(n)/in & 0 \end{pmatrix} \begin{pmatrix} \tilde{w}_1(n) \\ \tilde{w}_2(n) \end{pmatrix} e^{inx}$$

$$= \sum_{n \neq 0} \begin{pmatrix} 0 & in \\ \beta_2(n)/in & 0 \end{pmatrix} \begin{pmatrix} \tilde{w}_1(n) \\ \tilde{w}_2(n) \end{pmatrix} e^{inx}.$$  

So, we conclude that $w = \mathcal{R}U$ satisfies an equation of the form (4.2) in which $g = \varphi_3$ and $S$ is a pseudodifferential operator of degree zero defined by

$$\overline{Sw_1}(n) = \left( \frac{\beta_1(n)}{in} \right)^2 \tilde{w}_1(n), \quad (4.3)$$

for $n \neq 0$. We observe that the eigenvalues of $A$ have the form $\pm \beta_1(k)$. On the other hand, using that $\phi_8$ takes values in $X_1$ and that $\phi_8(0) = D\phi_8(0) = 0$, then we find that $g(w_1, w_2) = \varphi_3(w)$ is Lipschitz from a small ball in $H^1 \times \tilde{H}^1$ into $\tilde{H}_1$ with $g(0, 0) = 0, Dg(0, 0) = 0$, as desired.
