Vibration Suppression via Time-delay Absorber
Described by Non-Linear Differential Equations

Abstract

The aim of this work is to control the main system behavior represented by a beam at simultaneous primary and internal resonance condition, where the system damage is probable. In this work, we present a comprehensive investigation of the effect of the time delay on the non-linear control of a beam when subjected to multi-external excitation forces. Control is conducted via time delay absorber to suppress chaotic vibrations. Multiple scale perturbation method is applied to obtain the solution up to the second order approximations. The different resonance cases are reported and studied numerically. The stability of the steady state solution for the selected resonance case is determined and investigated applying Rung-Kutta fourth order method and frequency response equation. Time delay absorber is more effective than ordinary absorber. The delay time is an important factor in selecting the absorber. Investigating the effect of time delay on main system behavior revealed that there is a critical value where below it vibration suppression is effective. The effects of the different parameters of the absorber on the system behavior are studied numerically. The reported results are compared to the available published work.

Keywords: Vibration control, Stability, Time delay, Absorber

1. Introduction

The study of vibrating structures has been a subject of a particular interest in recent years. This is due to the fact that structures under multi-external excitation forces appear in various fields of fundamental and applied science [1-3]. Among these studies, particular attention had been paid to the dynamical behavior of beams. It was shown that when the beam is not highly loaded, its dynamics could be explained by the classical Duffing oscillator [2]. In [3] the authors used the nonlinearity of a foundation and showed that the behavior of the beam could be
expressed by a $\phi^6$ potential. Another important center of the interest is the study of vibrating structures under active control [4-7]. In [5], Morgan et al. proposed a semi-active piezoelectric absorber for suppressing harmonic excitations with varying frequency. Aida et al. [6] proposed a plate type dynamic vibration absorber to control the vibration of plates. In [7] the authors used the beam-type vibration absorber to control the bending vibration of a beam in this case; the beam (or plate) is assumed to be in the linear dynamics. Non-linearities necessarily introduce a whole range of phenomena that are not found in linear systems [8], including jump phenomena, occurrence of multiple solutions, modulations, shift in natural frequencies, the generation of combination resonances and chaotic motions [9–10]. In such systems the vibrations are needed to be controlled to minimize or eliminate the hazard of damage or destruction. There are two main regimes for vibration control. They are passive and active control. One of the most effective tools of passive vibration control is the dynamic absorber or the damper or the neutralizer [11]. In [12] the authors proposed an approximate condition for escape from the potential well by comparing the maximum energy of the motion with barrier of the potential. Lee et al. [13] demonstrated a dynamic vibration absorber system, which can be used to reduce speed fluctuations in rotating machinery. Eissa [14] has shown that to control the vibration of a system subjected to harmonic excitations, the fundamental or the first harmonic absorber is the most effective one. In [15], the authors considered such a problem in linear structures and showed that time-delay can even lead to the instability of the whole structure. Eissa et. al. [16-17] investigated saturation phenomena in non-linear oscillating systems subject to multi-parametric and/or external excitations. The system represents the vibration of a single-degree-of-freedom cantilever or the wing of an aircraft. They reported the occurrence of saturation phenomena at different parameters values. They applied saturation values of different parameters as optimum working conditions for vibration suppression of the cantilever. In ref [18], the authors considered such a problem in linear structures and showed that time-delay can even lead to the instability of the whole structure. Nana et al [19-21] studied the modeling and optimal active control with time delay dynamics of a strongly nonlinear beam. They investigated the control by a sandwich beam and one using piezoelectric absorber. Yaman [22] studied the primary and parametric resonances of a directly and parametrically excited nonlinear cantilever beam of varying orientation with time-delay state feedback. The perturbation method was used to obtain the bifurcation equation of the linear dynamic system. A control law based on time-delay feedback is used. Maccari [23-24] studied the vibration control for parametrically excited Lienard systems and vibration amplitude control for a van der Pol-Duffing oscillator with time delay. Using the asymptotic perturbation method, the best choices of the feedback gains and the time delay from the viewpoint of vibration control are found. In many cases the amplitudes of periodic solutions do not correspond to the technical requirements. It is demonstrated that if the vibration control terms are added, stable periodic solutions with arbitrarily chosen amplitude can be accomplished. Therefore the results obtained show that an effective vibration
amplitude control is possible if appropriate time delay and feedback gains are chosen.

The objective of this work is to study the vibration of a damped beam subject to multi-external excitation forces. The model is represented by two-degree-of-freedom system consisting of the main system and the absorber. The multiple time scale perturbation technique is applied throughout to get an approximate solution up to the second order. The stability of the system is investigated numerically applying both phase-plane and frequency response functions. The effects of the different parameters of the absorber on system behavior are studied numerically. Some optimal parameters for the absorber are determined. Comparison with the available published work is reported.

2. Mathematical Modeling

The modified governing equations of the mechanical systems under control are given by equations [15].

\[
\ddot{X}_1(t) + \varepsilon(\lambda_1 + \alpha)\dot{X}_1(t) + \alpha^2 X_1(t) + \varepsilon c X_1(t) + \varepsilon d X_1(t) - \varepsilon \beta X_2(t) - \varepsilon \alpha X_2(t) = \sum_{j=1}^{3} F_j \cos(\Omega_j t)
\]

\[
\ddot{X}_2(t) + \varepsilon(\lambda_2 + \mu \alpha)\dot{X}_2(t) + \alpha^2 X_2(t) = \varepsilon \mu \beta X_1(t) + \varepsilon \mu \alpha \dot{X}_1(t)
\]  

The main system is exited by multi-external forces, \(X_1, \dot{X}_1, \ddot{X}_1\) are the displacement, velocity and acceleration of the beam respectively and \(X_2\) is the control force, \(\lambda_1\) and \(\lambda_2\) are the non-dimensionless damping coefficient of the two system respectively, \(c, d\) and \(\mu\) are the other characteristic coefficient of the structure, \(\alpha\) and \(\beta\) are the non-dimensionless control gain parameters and \(F_j, \Omega_j\) are the external excitation forces, the natural frequencies respectively. The delay is materialized by the fact that the control system doesn't act at the same time with excited structure. Mathematically, this effect is taken into account by using the retarded functional differential equations \[18, 19, 20\]. Thus for a controlled system with delay, the differential equation given by (1) becomes:

\[
\ddot{X}_1(t) + \varepsilon(\lambda_1 + \alpha)\dot{X}_1(t) + \alpha^2 X_1(t) + \varepsilon c X_1(t) + \varepsilon d X_1(t) - \varepsilon \beta X_2(t) - \varepsilon \alpha X_2(t) = \sum_{j=1}^{3} F_j \cos(\Omega_j t)
\]

\[
\ddot{X}_2(t) + \varepsilon(\lambda_2 + \mu \alpha)\dot{X}_2(t) + \alpha^2 X_2(t) = \varepsilon \mu \beta X_1(t - t_q) + \varepsilon \mu \alpha \dot{X}_1(t - t_q)
\]  

Where \(t_q\) and \(t_q\) are the time delays for the displacement and velocity feedback in the system respectively.

2.1. Perturbation analysis

Multiple scale perturbation method \[25-27\] is conducted to obtain an approximate solution for Eqs. (2) Assuming the solution in the form:

\[
x_1(t; \varepsilon) = x_{10}(T_0, T_1) + \varepsilon x_{11}(T_0, T_1) + \varepsilon^2 x_{12}(0)
\]

\[
x_2(t; \varepsilon) = x_{20}(T_0, T_1) + \varepsilon x_{21}(T_0, T_1) + \varepsilon^2 x_{22}(0)
\]
and the time derivatives became
\[
\frac{d}{dt} D_0 + \varepsilon D_1 \quad \text{and} \quad \frac{d^2}{dt^2} = D_0' + 2\varepsilon D_0 D_1 + \varepsilon^2 D_1^2 \tag{5}
\]
where \( T_0 = \varepsilon^0 t \). (n=0, 1) are the fast and slow time scales respectively.

Substituting Eqs. (3), (4) and (5) into Eqs. (2) and equating the coefficients of the same power of \( \varepsilon \) in both sides, we obtain

\[
(D_0^2 + \omega_1^2) x_{10} = \frac{1}{2} \sum_{j=1}^{n} F_j \left( e^{i\Omega_j T_0} + e^{-i\Omega_j T_0} \right) \tag{6}
\]

\[
(D_0^2 + \omega_2^2) x_{20} = 0 \tag{7}
\]

\[
(D_0^2 + \omega_1^2) x_{11} = -2D_1 D_0 x_{10} - (\lambda_1 + \alpha) D_0 x_{10} - c x_{10}^3 - dx_{10}^5
+ \beta x_{20} + \alpha D_0 x_{20} \tag{8}
\]

\[
(D_0^2 + \omega_2^2) x_{21} = -2D_1 D_0 x_{20} - (\lambda_2 + \mu\alpha) D_0 x_{20} + \mu\beta x_{10} (T_0 - t_q, T_1) + \mu\alpha D_0 x_{10} (T_0 - t_q, T_1) \tag{9}
\]

The solution of Eqs. (6) and (7) can be expressed in the form

\[
x_{10} = A_{10} \exp(i \omega_1 T_0) + \frac{1}{2} \sum_{j=1}^{n} P_j \exp(i \Omega_j T_0) + cc \tag{10}
\]

\[
x_{20} = A_{20} \exp(i \omega_2 T_0) + cc \tag{11}
\]

Where \( P_j = \frac{F_j}{\omega_1^2 - \Omega_j^2} \) and \( A_{10}, A_{20} \) are complex functions in \( T_1 \), which can be determined from eliminating the secular terms at the next approximation, and \( cc \), stands for the conjugate of the preceding terms. Substituting Eqs. (10) and (11) into Eq. (8), eliminating the secular terms, then the first order approximation is given by:

\[
x_{11} = A_{11} \exp(i \omega_1 T_0) - \frac{i}{2} (\lambda_1 + \alpha) \sum_{j=1}^{n} E_j \exp(i \Omega_j T_0) + c \left[ -A_{10}^3 \exp(3i \omega_1 T_0) \right]
+ 3A_{10}^3 \sum_{j=1}^{n} E_j \exp(i \Omega_j T_0) + \frac{3}{2} A_{10}^2 \sum_{j=1}^{n} E_j \exp(i (2\omega_1 + \Omega_j) T_0) + \frac{3}{2} A_{10} \sum_{j=1}^{n} E_j \exp(i (2\omega_1 - \Omega_j) T_0)
+ 3A_{10}^3 \sum_{j=1}^{n} E_j \exp(i (\omega_1 + \Omega_j + \Omega_k) T_0) + \frac{3}{2} A_{10} \sum_{j=1}^{n} E_j \exp(i (\omega_1 + \Omega_j - \Omega_k) T_0)
+ 3A_{10}^3 \sum_{j=1}^{n} E_j \exp(i (\omega_1 - \Omega_j + \Omega_k) T_0) + \frac{3}{2} A_{10} \sum_{j=1}^{n} E_j \exp(i (\omega_1 - \Omega_j - \Omega_k) T_0)
+ d \left[ \frac{1}{24 \omega_1^4} A_{10}^4 \exp(i (5\omega_1) T_0) + \frac{5}{8 \omega_1^2} A_{10}^4 T_{10} \exp(i (3\omega_1) T_0) \right]
- \frac{5}{2} \sum_{j=1}^{n} E_j A_{10}^4 \exp(i (4\omega_1 + \Omega_j) T_0) - \frac{5}{2} \sum_{j=1}^{n} E_j A_{10}^4 \exp(i (4\omega_1 - \Omega_j) T_0)
\]
\[-15 A_{10}^2 T_{10}^2 \sum_{j=1}^{3} E_1 \exp(i \Omega_j) T_0 - 10 A_{10}^3 T_{10} \sum_{j=1}^{3} E_2 \exp(i (2 \omega_1 + \Omega_j) T_0)\]

\[-10 \sum_{j=1}^{3} E_j A_{10}^3 T_{10} \exp(i (2 \omega_1 - \Omega_j) T_0) - \frac{5}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} E_{11} A_{10}^3 \exp(i (3 \omega_1 + \Omega_j + \Omega_k) T_0)\]

\[-10 \sum_{j=1}^{3} E_{12} A_{10}^3 \exp(i (3 \omega_1 + \Omega_j - \Omega_k) T_0) - \frac{5}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} E_{3} A_{10}^3 \exp(i (3 \omega_1 - \Omega_j + \Omega_k) T_0)\]

\[-\frac{15}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} E_{13} A_{10}^3 \exp(i (\omega_1 + \Omega_j + \Omega_k) T_0) - \frac{15}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} E_{15} A_{10}^3 \exp(i (\omega_1 - \Omega_j - \Omega_k) T_0)\]

\[-15 \sum_{j=1}^{3} \sum_{k=1}^{3} E_{14} A_{10}^3 \exp(i (\omega_1 - \Omega_j - \Omega_k) T_0) - 15 \sum_{j=1}^{3} \sum_{k=1}^{3} E_{16} A_{10}^3 \exp(i (\omega_1 - \Omega_j + \Omega_k) T_0)\]

\[-5 \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} E_{17} A_{10}^3 \exp(i (2 \omega_1 + \Omega_j + \Omega_k + \Omega_l) T_0) - \frac{15}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} E_{18} A_{10}^3 \exp(i (2 \omega_1 + \Omega_j + \Omega_k - \Omega_l) T_0)\]

\[-\frac{15}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} E_{19} A_{10}^3 \exp(i (2 \omega_1 + \Omega_j - \Omega_k - \Omega_l) T_0) - 2 \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{20} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m) T_0)\]

\[-\frac{5}{4} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{21} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m) T_0) - \frac{5}{3} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{22} A_{10}^3 \exp(i (\omega_1 + \Omega_k - \Omega_m) T_0)\]

\[-\frac{15}{8} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{23} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m) T_0) - \frac{1}{3} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{24} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m) T_0)\]

\[-\frac{5}{2} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{25} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m) T_0) - \frac{5}{16} \sum_{j=1}^{3} \sum_{k=1}^{3} \sum_{l=1}^{3} \sum_{m=1}^{3} E_{26} A_{10}^3 \exp(i (\omega_1 + \Omega_k + \Omega_m - \Omega_n) T_0)\]

\[+ \beta A_{20} E_{25} \exp(i \omega T_0) + i \omega_2 \alpha A_{20} E_{25} \exp(i \omega T_0) + cc\]  \hspace{1cm} (12)

Where $E_s (s=1,2,\ldots,25)$ are complex functions in $T_1$ and $j=(1, 2, 3)$. From Eqs. (10), (11) and (12) into Eq. (9) and eliminating the secular terms the solution is given by:

\[x_{21} = A_{22} \exp(i \omega T_0) + \mu \beta A_{10} H_1 \exp(i \omega T_0) + \frac{1}{2} P_j \mu \beta H_2 \exp i \Omega_j (T_0 - t_q)\]

\[+ \mu \alpha (i \omega) A_{10} H_1 \exp(i \omega T_0) + \frac{1}{2} P_j \mu \alpha (i \Omega_j) H_2 \exp i \Omega_j (T_0 - t_q) + cc\]  \hspace{1cm} (13)

Where $H_s (s=1,2)$ are complex functions in $T_1$ and $j=(1,\ldots,3)$.

The reported resonance cases at this approximation order are:

(a) Trivial resonance: $\Omega_1 \approx \omega_1 \approx \omega_2 = 0$

(b) Primary resonance: $\Omega_1 \approx \omega_1 , \Omega_1 \approx \omega_2$

(c) Sub-harmonic resonance: $\Omega_1 \approx 2\omega_1, \Omega_1 \approx 3\omega_1 , \Omega_2 \approx 2\omega_2, \Omega_3 \approx 3\omega_2$

(d) Internal resonance: $\omega_1 \approx \omega_2$
Simultaneous or incident resonance: Any combination of the above resonance cases is considered as simultaneous resonance.

2.2 Stability of the system

Introducing the detuning parameters $\sigma_j$ and $\rho_j$ for the primary and internal resonance cases to convert the small-divisor terms into the secular terms, according to:

$$\Omega_j \equiv \omega_j + \varepsilon \sigma_j, \quad \Omega_j \equiv \omega_j + \varepsilon \rho_j$$

This case represents the system worst case (confirmed numerically). Substituting Eq. (14) into Eqs. (8) and (9) and eliminating the secular terms, leads to the solvability conditions for the first order approximation noting that $A_{10}$ and $A_{20}$ are functions in $T_1$ we get

$$i \omega_1[2D_1A_{10} + (\lambda_1 + \alpha)A_{10}] + \frac{1}{2}(\lambda_1 + \alpha)P_j\Omega_j e^{i\sigma_{11}T_1} + 3cA_{10}^2\overline{A_{10}} + 3cA_{10}\overline{A_{10}}P_j e^{i\sigma_{11}T_1} + 10dA_{10}^2\overline{A_{10}}^2 + 15dA_{10}\overline{A_{10}}^2P_j e^{i\sigma_{11}T_1} = 0$$

$$i \omega_2[2D_1A_{20} + (\lambda_2 + \mu \alpha)A_{20}] - \frac{1}{2}[\mu \beta P_j e^{-i\Omega_j t_q} + i \mu \omega_2 P_j e^{-i\Omega_j t_q}] e^{i\rho_{11}T_1} = 0$$

Putting $A_{10} = \frac{1}{2}a_1(T_1)e^{ip_1(T_1)}$, $A_{20} = \frac{1}{2}a_2(T_1)e^{ip_1(T_1)}$

where $a_1, a_2$ and $p_1, p_1$ are the steady state amplitudes and the phases of the motion respectively. Substituting Eq. (17) into Eqs. (15) and (16) and separating real and imaginary parts yields,

$$a_1' = -\frac{1}{2}(\lambda_1 + \alpha)a_1 - \frac{(\lambda_1 + \alpha)\Omega_j P_j}{2\omega_1} \cos \theta_j - \left[\frac{3ca_1^2P_j}{4\omega_1} + \frac{15da_1^4P_j}{16\omega_1}\right] \sin \theta_j$$

$$a_2' = \frac{3ca_1^3}{8\omega_1} + \frac{10da_1^5}{32\omega_1} + \frac{(\lambda_1 + \alpha)\Omega_j P_j}{2\omega_1} \sin \theta_j + \left[\frac{3ca_1^2P_j}{4\omega_1} + \frac{15da_1^4P_j}{16\omega_1}\right] \cos \theta_j$$

$$a_2' = -\frac{(\lambda_2 + \mu \alpha)a_2}{2} + \frac{\mu \omega_2 P_j}{2\omega_2} \cos(\varphi_j - \Omega_j t_q) + \frac{\mu \beta P_j}{2\omega_2} \sin(\varphi_j - \Omega_j t_q)$$

$$a_2' = \frac{\mu \omega_2 P_j}{2\omega_2} \sin(\varphi_j - \Omega_j t_q) - \frac{\mu \beta P_j}{2\omega_2} \cos(\varphi_j - \Omega_j t_q)$$

where

$$\theta_j = \sigma_j T_1 - p_1, \quad \varphi_j = \rho_j T_1 + \phi_1 - p_1$$

For steady state solutions, $a_1' = a_2' = \theta' = \varphi' = 0$. Then from Eq. (22), we get:

$$p_1' = \sigma_j, \quad \phi_1' = \sigma_j - \rho_j$$

Then it follows from Eqs. (18)-(21) that the steady state solutions are given by
Vibration suppression via time-delay absorber

\[-\frac{1}{2}(\lambda_1 + \alpha)a_1 - \frac{(\lambda_1 + \alpha)\Omega_j P_j}{2\omega_1}\cos \theta_j - \frac{3ca_1^2 P_j}{4\omega_1} + \frac{15da_1^4 P_j}{16\omega_1}\sin \theta_j = 0 (24)\]

\[a_i\sigma_j = \frac{3ca_j^3}{8\omega_1} + \frac{10da_j^5}{32\omega_1} - \frac{\lambda_1 + \alpha)\Omega_j P_j}{2\omega_1}\sin \theta_j + \frac{3ca_j^2 P_j}{4\omega_1} + \frac{15da_j^4 P_j}{16\omega_1}\cos \theta_j (25)\]

\[-\frac{(\lambda_2 + \mu \alpha)a_2}{2} + \frac{\mu \alpha \Omega_j P_j}{2\omega_2}\cos(\varphi_j - \Omega_j t_q) + \frac{\mu \beta j P_j}{2\omega_2}\sin(\varphi_j - \Omega_j t_q) = 0 (26)\]

\[a_2 \rho_j = \frac{\mu \alpha \Omega_j P_j}{2\omega_2}\sin(\varphi_j - \Omega_j t_q) + \frac{\mu \beta j P_j}{2\omega_2}\cos(\varphi_j - \Omega_j t_q) (27)\]

From Eqs. (24)- (27) we have the following two cases:

1. \(a_i \neq 0, a_2 = 0\)
2. \(a_i = 0, a_2 \neq 0\)

Table 1 gives the final results of the frequency response equations.

<td>(a_i = 0, a_2 \neq 0)</td>
<td>(\rho_j^2 + k_1 = 0)</td>
</tr>
</tbody>
</table>

Where \(k_1, k_2, k_3\) are defined in the appendix.

The stability of the linear solution of the obtained fixed points will be determined as follows. Consider \(A_{10}, A_{20}\) in the form:

\[A_{10} = \frac{1}{2}[p_1 - iq_1]e^{iv_1 T_1}, A_{20} = \frac{1}{2}[p_2 - iq_2]e^{iv_2 T_1}\]  

(28)

where \(p_1, p_2, q_1, q_2\) are real and \(v_1 = \sigma_j, v_2 = \rho_j\). Substituting Eq. (28) into the linear part of Eqs. (15) and (16) and separating real and imaginary part yields,

\[p_1' + v_1 q_1 + \frac{(\lambda_1 + \alpha)}{2} p_1 = 0\]  

(29)

\[q_1' - v_1 p_1 + \frac{(\lambda_1 + \alpha)}{2} q_1 = 0\]  

(30)

\[p_2' + v_2 q_2 + \frac{(\lambda_2 + \mu \alpha)}{2} p_2 = 0\]  

(31)

\[q_2' - v_2 p_2 + \frac{(\lambda_2 + \mu \alpha)}{2} q_2 = 0\]  

(32)

The eigen equation of the above system of equations is obtained from:

\[\begin{vmatrix}
2(\lambda_1 + \alpha) & -\lambda & 0 & 0 \\
-\nu_1 & 2(\lambda_1 + \alpha) & -\lambda & 0 \\
0 & 0 & 2(\lambda_2 + \mu \alpha) & -\lambda \\
0 & 0 & -\nu_2 & 2(\lambda_2 + \mu \alpha) - \lambda
\end{vmatrix} = 0 (33)\]
The eigenvalues are given by the equation
\[ \lambda^4 + r_1 \lambda^3 + r_2 \lambda^2 + r_3 \lambda + r_4 = 0 \]  
(34)

Where, \( r_1, r_2, r_3 \) and \( r_4 \) are functions of the equations parameters and they are given in the appendix. According to the Routh-Hurwitz criterion, the necessary and sufficient conditions for all the roots of Eq. (34) to possess negative real parts is that
\[ r_1 > 0, r_1 r_2 - r_3 > 0, r_3 (r_1 r_2 - r_3) - r_1^2 r_4 > 0, \quad r_4 > 0 \]  
(35)
This means that the system is stable if and only if equation (35) is verified.

3. Results and discussion

The differential equation of the main system is solved numerically (applying Rung-Kutta 4th order method) at primary resonance case without absorber as shown in Fig. 1. The steady state response is about 2100\% of (the fundamental) excitation amplitude \( F \). The system is stable with fine limit cycle, denoting that the system is approximately free from dynamic chaos.

Fig.1. Response of the main system without absorber at primary resonance case
\[ \Omega_1 \cong \omega_1 \quad (\lambda_i = 0.009, \alpha = 0.0001, \beta = 0.2, c = 0.013, d = -0.0008, \Omega_i = 1.06, \omega_1 = 1.06, \Omega_2 = 2.12, \Omega_3 = 4.24, F_1 = 0.2, F_2 = 0.3, F_3 = 0.4) \]

3.1. Effect of the absorber without delay time:

Fig.2. illustrates the results at simultaneous primary resonance when the absorber (without delay time) is effective, i.e., when \( \Omega_1 \cong \omega_2 \). It can be seen for the main system that the steady state amplitude is reduced to about 14\% from its value without absorber. The absorber steady state amplitude is about 19\% of the main system amplitude without absorber. This means that the effectiveness of the absorber \( E_a \) (\( E_a = \) the steady state amplitude of the main system without absorber/ the steady state amplitude of main system with absorber) is about 700.
Vibration suppression via time-delay absorber

Fig. 2. Response of the main system and absorber at simultaneous
Primary resonance case $\Omega_1 \cong \omega_1$, without time delay.

\[ \mu = 0.6, \lambda_1 = 0.009, \lambda_2 = 0.07, \alpha = 0.0001, \beta = 0.2, c = 0.013, d = -0.0008, a = 1.0036 \]
$\omega_1 = 1.06, \omega_2 = 1.06, \Omega_1 = 1.06, \Omega_2 = 2.12, \Omega_3 = 4.24, F_1 = 0.2, F_2 = 0.3, F_3 = 0.4$

3.2. Effects of delay time absorber on the system behavior:

Delay time absorber is considered instead of ordinary absorber. The effect of delay time on systems response was studied numerically. It has been noticed that up to $t_q = 0.3$ the main system has a steady state amplitude of about 12% from its value without absorber within the selected values for the parameters. When $t_q$ was increased a jump has been occurred for the steady state amplitude to about 119% of the main system without absorber. This means that the operating range for the system is better when $t_q \leq 0.3$, as shown in Fig. 3.

(a) $t_q = 0.01$
Fig. 3. Effect of delay time on system steady state amplitude.

3.3. Effects of different parameters

The effects of different parameters were investigated by solving Eqs. (24-27). The results are summarized in Tables 2 and 3. They are illustrated graphically in Figs. 5 and 6.

4. Conclusions

The vibrations of a second order, non-linear mechanical system and time delay absorber are investigated. Multiple time scale perturbation technique is applied to
determine semi-closed form solutions for the coupled differential equations up to the second order approximations. To study the stability of the system, both the frequency response equations and the phase-plane technique are applied. From the above study the following may be concluded.

1. The worst behavior of the main system occurs at primary resonance case where the steady state response is about 2100% of the fundamental excitation amplitude $f_1$.
2. The vibration of the main system can be reduced via an ordinary absorber and the effectiveness of the absorber is about $E_a = 700$, at simultaneous resonance case $\Omega_1 \approx \omega_1$, $\Omega_2 \approx \omega_2$.
3. The steady-state amplitudes of the main system are monotonic decreasing functions of $\omega_2, \lambda, \Omega_1$ and monotonic increasing functions of the parameters $\beta, f_1, \alpha, \lambda_1, \Omega_1, \mu, \epsilon$.
4. For negative and positive values of $\omega_1$ the curve is bent to the right or the left leading to the occurrence multi-valued amplitudes function.
5. Delay time absorber is more effective for vibration suppression than the ordinary one.
6. Optimum working conditions as $E_a = 1250$ are obtained when $t_q \leq 0.3$.
7. References [22-24] studied the vibration amplitude control with delay time feedback but without any absorber. Ref. [21] studied active control with delay time using piezoelectric absorber but it is limited to a single external force. The study in this paper is an expansion to illustrate the response and the stability of the two degree of freedom $(x_1, x_2)$ of the system when subjected to multi external forces. They demonstrate the effectiveness of the delay time absorber. Unfortunately none of the above mentioned references is directly related to our work. The only point of agreement is the effectiveness of the absorber to control vibration.
