Abstract

We prove that a right self right perfect algebra which is at most countable dimensional modulo their Jacobson radical is right artinian.

Mathematics Subject Classification: 16D50, 16L60

Keywords: self injective rings, right perfect rings, quasi-frobenius rings

1. Introduction

In this note we present a proof for algebra R over a field K which is at most countable dimensional modulo their Jacobson radical i.e. $R/\text{Rad}(R)$ is at most N_0

This includes for example the important situation when $R/\text{Rad}R$ is not only semisimple but also finite dimensional'

Let R be a ring with identity and $\text{Rad}R$ is its Jacobson radical. If R is right perfect (i.e. $R/\text{Rad}R$ is semisimple and $\text{Rad}R$ is left T-nilpotent) then

$R/\text{Rad}R$ is semisimple and hence $(R/\text{Rad}R)_R$ and ${}_R(R/\text{Rad}R)$ are semisimple right and left R -module.

Note that since $R/\text{Rad}R$ is semisimple then an R -module M is semisimple iff it is cancelled by $\text{Rad}R$. Indeed every simple is cancelled by $\text{Rad}R$ and if $\text{Rad}M=0$ then M has $R/\text{Rad}R$ -module structure which is semisimple, therefore M is semisimple as the lattice of R -submodules and $R/\text{Rad}R$ sub-modules coincide in this case.

$(R/\text{Rad}R)_R$ is semisimple and finitely generated, so it has a composition series

$$\text{i.e.} \quad J/J^2 \subset J^2/J^3 \subset \dots \subset J^{n-1}/J^n$$

is of length $n-1$ where each J^k/J^{k+1} is semisimple for all k .

Note that if R is right self injective then each decomposable (eR) has simple socle.

Indeed if we have a nontrivial decomposition of the $\text{socle}(eR) = M \oplus N$

Then we can find $E(M)$ and $E(N)$ injective hulls of M, N contained in eR and we obtain

$eR = E(M) + E(N)$ nontrivial decomposition that is a contradiction.

Note also that if R is right self injective right perfect then for each simple Right R -module, the left module $\text{Hom}(S, R)$ is simple.

First $\text{Hom}(S, R)$ is non zero. Looking for the isomorphism types of indecomposable modules eR , these are projective, local and the cover of some simple R -module.

The number of isomorphism types of such modules equals the number of isomorphism types of simple modules equal t , say.

Moreover since the indecomposable eR 's also injective with simple socle we see that they are isomorphic if and only if their socle isomorphic. This shows that the distinct types of isomorphism of simples occurring as socle of some eR is also t , and so each simple S must appear as a socle of some eR (i.e. it embeds in R) this shows that, for each simple R -modules S . If $f, g \in \text{Hom}(S, R)$ and $\text{Hom}(S, R) \neq 0$

$$f : S \rightarrow R \quad f \neq 0, \text{ then}$$

Is a monomorphism and since R_R is injective then there is some $h : R \rightarrow R$

Such that $h \circ f = g$. If $f(x) = xc \quad \forall x \in R$ we get $f(x).c = g(x)$ i.e. $f.c = g$ in

$\text{Hom}(S, R)$, this shows that $\text{Hom}(S, R)$ is generated by $f \neq 0$ so it is simple.

In particular since each simple module embeds in R which is right self injective, it follows that R is injective cogenerator in the category of right R -module, i.e. it is a right PF (Pseudo- Frobenius) ring.

2. Main Results

Let s be a set of representatives' for simple right R -modules and let $t=|s|$ and $R/\text{Rad}R = \bigoplus S^{K_s}$. Let $W = \text{socle}(R_R)$ be the right socle of R so W is an R -sub-bimodule of R .

Since each indecomposable module (Re) has simple socle, we have $\text{Length}(W)$ equals the number of terms in the indecomposable decomposition $R = \bigoplus_s Re$ which equals $\text{length}(R/\text{Rad}R)_R$, since each

Indecomposable (Re) is local

Let $W = \bigoplus S^{P_s}$ we have $\sum_{S \in s} P_s = \sum_{S \in s} K_s$

Proposition 1

Let R be a right self injective right perfect ring then the set $\{Hom(S, R); S \in s\}$ is a set of representatives for simple left R -modules.

In particular $Hom(S, R)$ and $Hom(T, R)$ are nonisomorphic for nonisomorphic, $S, T \in R$

Proof

Since R is right self injective the monomorphism

$$0 \rightarrow W \rightarrow R, \quad \text{gives rise to the epimorphism} \\ Hom(R, R) \rightarrow Hom(W, R) \rightarrow 0$$

Note that

$$Hom(W, R) = \bigoplus Hom(S, R)$$

Since $Hom(S, R) \neq 0 \forall S \in s$, we have

$$Hom(W, R) = \bigoplus Hom(S, R)^{P_s},$$

has length equal to the length $W = \sum_{S \in s} P_s = \text{length}(R/\text{Rad}R)_R$

By classical Wedderburn –Artin Theorem:

$$\text{length}_R(R/\text{Rad}R) = \text{length}_R(R/\text{Rad}R)$$

Since $Hom(W, R)$ is semisimple, the kernel of $R \rightarrow Hom(W, R)$

Contains $\text{Rad}R$ and therefore since

$$\text{length}_R(R/\text{Rad}R) = \text{length}_R Hom_R(W, R),$$

we obtain $R/\text{Rad}R \cong Hom(W, R)$ as left R -module.

This shows that all types of isomorphism of simple left R -modules are found among components of $Hom(W, R)$ and the statement is proved

Note: we note that the above proof further shows that there is an exact sequence of left R-modules

$$0 \rightarrow \text{Rad}R \rightarrow R \rightarrow \text{Hom}(W, R) \rightarrow 0$$

This means that

$$\{ r \in R, \text{ such that } rW = 0 \} = \text{Rad}R. \text{ That is } \text{ann}_R(W) = \text{Rad}R$$

This shows that W is also semisimple as a left R-module, i.e. the right socle of R is contained in the left socle, and hence the left and the right socle or the right PF ring coincide.

For a right R-module M, denote $M^* = \text{Hom}(M, R)$ this is a left R-module.

Proposition 2

Let R be a right injective ring and let M be a right R-module such that there is an exact sequence

$$0 \rightarrow S_R \rightarrow M_R \rightarrow L_R^{(\alpha)} \rightarrow 0$$

With S, L simple modules and assume $S = \text{socle}(M)$, $L_R^{(\alpha)}$ denote the coproduct of α copies of L_R . Then M^* is local left R-module with unique maximal ideal

$$S^\perp = \{ f \in \text{Hom}(M, R); f|_S \neq 0 \}$$

Which is semisimple isomorphic to $(L_R^*)^{(\alpha)}$

Proof

Since

$$0 \rightarrow S_R \rightarrow M_R \rightarrow L_R^{(\alpha)} \rightarrow 0$$

is an exact sequence, so we get the exact sequence,

$$0 \rightarrow \text{Hom}(L^{(\alpha)}, R) \rightarrow \text{Hom}(M, R) \rightarrow \text{Hom}(S, R) \rightarrow 0$$

That is

$$0 \rightarrow (L^*)^\alpha \rightarrow M^* \rightarrow S^* \rightarrow 0$$

The kernel of the morphism

$$M^* = \text{Hom}(M, R) \xrightarrow{\gamma^*} S^* = \text{Hom}(S, R)$$

$$\text{Is } \{ f \in \text{Hom}(M, R); f|_S \neq 0 \} = S^\perp$$

Hence $S^\perp \cong (L^*)^\alpha$ which is left semisimple module since it is cancelled by $\text{Rad}R$.

Now since M has simple socle, and its socle embeds in R which is injective it follows that M embeds in R. We note that M^* is generated by any $f \notin S^\perp$ which will show

that M^* is cyclic. Indeed such f must be a monomorphism and given any other $h: M \rightarrow R$.

By injectivity of R_R there is $g \in \text{Hom}(R, R)$ such that $g \circ f = h$. If $g(x) = cx$ for $c \in R$ then we have $h = c.f$ in M^* . This shows that $f.R = M^*$ which shows that $S^\perp$ is the only maximal submodules of the cyclic left R -module M^* , that ends of the proof.

Note that the fact that M^* is local can also be proved by embedding M in some indecomposable (eR) for an indecomposable idempotent e , and then, by applying the exact functor $\text{Hom}(-, R)$ one obtain an epimorphism

$$\text{Hom}(eR, R) = eR \rightarrow M^*, \text{ and so } M^* \text{ is local because } eR \text{ is.}$$

Let α be the largest cardinality for which there is a right R -module M with simple socle and such that $M / (\text{socle}(M)) \cong L^\alpha$ for some simple module L .

Such cardinality exists, since any such module is contained in R because R is injective. In fact if W_1 is the second socle of R , then $\alpha \leq \text{length}(W_2 / W_1)$. we note that if α is infinite this is an equality.

Indeed if for each simple modules S, L we denote by

$$\alpha_{S,L} = [(E(S) / S) : L] \text{ -the multiplicity of } L \text{ in the second socle of the injective hull } E(S) \text{ of } S, \text{ then } \alpha = \max_{S,L} (\alpha_{S,L}).$$

$$\text{Therefore } \alpha \leq \sum_{S,L \in S} \alpha_{S,L} \leq n\alpha = \alpha \text{ if } \alpha \text{ is infinite.}$$

We note also that if $\sum_k$ is the k^{th} socle then the $\text{length}(W_k / W_{k-1}) \leq \alpha$; this follows by induction on k .

If this is true for k , then there is an embedding

$$W_k / W_{k-1} \hookrightarrow R^{(\alpha)}$$

And therefore we have

$$\text{length}(W_{k+1} / W_k) \leq \text{length}(W_1 / W_0)^{(\alpha)} = \alpha \times \alpha = \alpha,$$

since α is infinite cardinal. So we have the following theorem:

Theorem

Let R be a right self injective right perfect algebra such that the dimension of each simple R -module is at most countable (equivalently the dimension of $R / \text{Rad} R$ is at most countable) hence R is countable, and hence right artinian

Proof

With the above notation, assume α is infinite. The length of each W_k/W_{k-1} is at most α , so since the dimension of each simple is at most $\aleph_0$, its dimension is at most $\aleph_0 \times \alpha = \alpha$ (since α is infinite).

Thus the dimension of R is at most α , and so it equals α (since $\text{length}(W_1/W_0) = \alpha$).

On the other hand, by proposition (2.2) there is a local left R -module M^* , with socle L^α for some simple L .

Note that $\dim(L^\alpha) \geq 2^\alpha$ and that there is an epimorphism $R \rightarrow M^*$

So $\dim(R) \geq 2^\alpha$, this is a contradiction.

By the result of Lawrence [3] R is right self injective countably generated algebra over a field so it is quasi-frobenius and hence right artinian.
