## Abstract

By studying a first order Briot-Bouquet vector differential equation we obtain conditions on the existence and uniqueness of solutions to higher order non-homogeneous vector differential equations. These solutions are vector functions whose components are complex valued holomorphic functions in the unit disc.

**Mathematics Subject Classification:** 32Axx, 32A10, 32A15, 34A30, 46E15, 46E20, 47A05

**Keywords:** Holomorphic function, Briot-Bouquet vector differential equation, Banach space, Hilbert space, operator equation

## 1. Introduction

The second order nonlinear differential equation

$$\frac{d^2x}{dt^2} = e^{\alpha\lambda t} x^{1+\alpha}, \quad (1.1)$$

where  $t, x$  are real variables and  $\alpha, \lambda$  are real parameters, as it is well known [1], is deduced from a very important second order nonlinear differential equation which has many physical applications, since it contains the Emden equation in astrophysics and the Fermi-Thomas equation in atomic physics. In addition to

this, (1.1) is closely related to a positive radial solution of an elliptic partial differential equation [8].

The asymptotic behavior of the solutions of the equation (1.1) was recently examined for  $-1 < \alpha < 0$  [9] and for  $\alpha < 0$  [10]. In doing so, the following result was proved and used.

**Lemma.** [9,10] Let  $w = w(\xi)$  be a solution of the Briot-Bouquet differential equation

$$\xi \frac{dw}{d\xi} = f(\xi, w), \quad (1.2)$$

where  $f(\xi, w)$  is a holomorphic function in the neighborhood of  $(\xi, w) = (0, 0)$ , with  $f(0, 0) = 0$  and  $f_w(0, 0) < 0$ . If 0 is an accumulation point of  $w(\xi)$  as  $\xi \rightarrow 0$  so that  $\arg \xi$  is bounded, then  $w(\xi)$  is the unique holomorphic solution.

In [5], by the use of a well known functional-analytic method, the study of the holomorphic solutions of the nonlinear scalar Briot-Bouquet differential equation

$$z \frac{df(z)}{dz} = G(f(z)), \quad (1.3)$$

where  $f(z)$  is a complex function and  $G(f(z))$  is holomorphic in  $f(z)$ , satisfying the conditions  $G(0) = 0$ ,  $G'(0) \neq 0$ , where  $G'(0)$  is the derivative of the function  $G(w)$  at  $w = 0$ , led to the existence of families of complex-valued solutions of the second order nonlinear differential equation

$$\frac{d^2 g(z)}{dt^2} = G(g(t)). \quad (1.4)$$

These solutions are periodic for  $G'(0) = -\tau^2 < 0$  and of exponential type for  $G'(0) = \tau^2 > 0$ . Moreover, these solutions imply the existence of infinite families of real-valued solutions, periodic and non-periodic, of a larger class of second order differential systems.

For the non-homogeneous equation  $Ly = g$ , where  $L$  is the operator defined by

$$Ly(z) = z^D y'(z) + A(z)y(z), \quad (1.5)$$

with  $D = \text{diag}(d_1, d_2, \dots, d_n)$ ,  $d_i$  nonnegative integers and  $A(z)$  an  $n \times n$  matrix of function holomorphic at  $z = 0$ , it was proved in [3] that its solvability depends on the solutions of the conjugate homogeneous equation  $L^*y = 0$ , where  $L^*$  is the conjugate operator of  $L$ . In particular it was shown that  $L^*y = 0$  has polynomial solutions if the constant matrix  $A$  has at least one non-positive integer eigenvalue.

The above problem was studied in the Banach space  $A_{p,n}$  of all  $n$ -vector functions whose components are holomorphic in the open unit disc  $\Delta = \{z : |z| < 1\}$  and  $p$  times continuously differentiable on the closed unit disc  $\bar{\Delta} = \{z : |z| \leq 1\}$ . The main difficulty encountered there was the description of the cokernel of the operator  $L$ .

The differential operator  $L : A_n \rightarrow A_0$ , defined by

$$Ly(z) = z^n y^{(n)}(z) + z^{n-1} a_1(z) y^{(n-1)}(z) + \dots + a_n(z) y(z), \quad (1.6)$$

where  $a_1(z), \dots, a_n(z)$  are holomorphic at  $z=0$  and  $A_p$  is the Banach space of functions  $u(z)$  holomorphic in  $\Delta$  and  $p$  times continuously differentiable on  $\bar{\Delta}$ , whose norm is given by

$$\|u(z)\|_p = \left\{ \max_{0 \leq i \leq p, |z|=1} |u^{(i)}(z)| \right\}$$

was studied in [2].

Using certain representation theorems from functional analysis, it was shown that the cokernel of the operator  $L$  is either zero dimensional or it is spanned by polynomials. Thus in the case when the non-homogeneous term is represented by

$$g(z) = \sum_{n=0}^{\infty} g_n z^n, \quad (1.7)$$

the solvability of the differential equation  $Ly = g$  in the Banach space  $A_p$ , is determined by a finite number of the coefficients in (1.7).

In [7] conditions were presented on the holomorphic coefficients  $A_j(z)$  of the higher order homogeneous differential equation

$$f^{(n)}(z) + A_{n-1}(z) f^{(n-1)}(z) + \dots + A_1(z) f'(z) + A_0(z) f(z) = 0 \quad (1.8)$$

So that all its solutions belong to the space  $H_p(\Delta)$  of holomorphic functions in the unit disc  $\Delta$ , which have  $p$  summable Taylor coefficients, i.e the space which consists of elements  $f(z) = \sum_{n=1}^{\infty} f_n z^{n-1}$ , holomorphic in  $\Delta$  that satisfy the

condition  $\sum_{n=1}^{\infty} |f_n|^p < \infty$ . Thus generalizing similar results, proved previously in the space  $H_2(\Delta)$ , concerning the second order homogeneous differential equation

$$f''(z) + A(z) f(z) = 0. \quad (1.9)$$

In this paper, by studying the homogeneous vector Briot-Bouquet differential equation

$$z \frac{df(z)}{dz} - A(z)f(z) = 0 \quad (1.10)$$

where  $f(z)$  is a vector-valued complex function and  $A(z)$  is an  $m \times m$  matrix with elements  $a_{ij}(z)$ ,  $i, j = 1, 2, \dots, m$ , holomorphic in  $\bar{\Delta}$ , we obtain conditions on the existence and uniqueness of holomorphic solutions to certain vector differential equations. Existence and uniqueness conditions of entire solutions are also predicted.

We follow the well-known functional analytic method, described in [4] and [5] that converts the question of the existence of holomorphic solutions of a differential equation into the study of an operator equation in an abstract Banach space, which is embedded in a separable Hilbert space. Moreover, the constructive nature of the method used, enables us to obtain information about the form of the existing solutions.

## 1. The abstract representation of a differential equation

Let  $H$  be an abstract, separable Hilbert space with an orthonormal basis  $\{e_n\}_1^\infty$  and  $H^m$  its product,  $H^m = \underbrace{H \times H \times \dots \times H}_{m\text{-times}}$ . The members  $f, g$  of  $H^m$  are denoted by  $f = (f_1, f_2, \dots, f_m)$  and  $g = (g_1, g_2, \dots, g_m)$ , where each  $f_i, g_i \in H$ ,  $i = 1, 2, \dots, m$  and their scalar product is defined by

$$\langle f, g \rangle = \sum_{i=1}^m (f_i, g_i),$$

where  $(f_i, g_i)$  denotes the scalar product in  $H$ . Every element  $f_i = \sum_{n=1}^\infty (f_i, e_n) e_n$  in  $H$  satisfies the condition  $\sum_{n=1}^\infty |(f_i, e_n)|^2 < \infty$ . We shall use the same symbol for the norm in both spaces  $H$  and  $H^m$ , denoted by  $\| \cdot \|$ .

We define the operator  $\bar{C}_0$  in  $H^m$  by the relation  $\bar{C}_0 f = (C_0 f_1, C_0 f_2, \dots, C_0 f_m)$ , where  $C_0$  is a diagonal operator acting on the elements  $e_n$ ,  $n = 1, 2, \dots$  of  $H$ , as follows  $C_0 e_n = n e_n$ ,  $n = 1, 2, \dots$  (see [4] for details).

The eigenvalues of  $\bar{C}_0$  in  $H^m$  are the values  $n = 1, 2, \dots$ , each of which has multiplicity  $m$ . Also, the eigenelements of  $\bar{C}_0$ , corresponding to an eigenvalue  $k$  are

$$\begin{aligned}
 e_{k1} &= (e_k, 0, 0, \dots, 0) \\
 e_{k2} &= (0, e_k, 0, \dots, 0) \\
 &\dots\dots\dots \\
 &\dots\dots\dots \\
 &\dots\dots\dots \\
 e_{km} &= (0, 0, 0, \dots, e_k)
 \end{aligned}$$

The set  $e_{ki}$ ,  $k=1,2,\dots$ ,  $i=1,2,\dots,m$  consisting of all the eigenelements of the operator  $\bar{C}_0$  is an orthonormal basis in the space  $H^m$ .

In fact if  $\langle e_{ki}, f \rangle = 0$ , for some  $f \in H^m$ , then  $\langle e_{ki}, f \rangle = (e_k, f) = 0, \forall k$ . This implies that  $f_i = 0$  for  $i=1,2,\dots,m$  and thus  $f = 0$ .

Similarly, we define the operator  $\bar{B}$  on  $H^m$  by  $\bar{B}f = (Bf_1, Bf_2, \dots, Bf_m)$ , where  $B$  is the compact, self-adjoint, diagonal, inverse operator of  $C_0$ , i.e.

$$Be_n = \frac{1}{n} e_n, \quad n=1,2,\dots \quad \text{and} \quad Bf_i = \sum_{n=1}^{\infty} \frac{1}{n} (f_i, e_n) e_n.$$

From the above it follows easily that  $\bar{B}$  is also a compact self-adjoint operator on  $H^m$  and since  $C_0$  has a self adjoint extension on the range of  $B$  [4], the same holds for  $\bar{C}_0$  in  $H^m$ , i.e. the inverse of  $\bar{C}_0$  is the compact operator  $\bar{B}$ .

Now let  $H_1$  be the Banach space consisting of those elements  $f_i \in H$ ,  $i=1,2,\dots$ , for which  $\sum_{n=1}^{\infty} |(f_i, e_n)| < \infty$ . The norm in  $H_1$  is defined by

$$\|f_i\|_1 = \sum_{n=1}^{\infty} |(f_i, e_n)|.$$

Let  $H_1^m$  denote the product space  $H_1^m = \underbrace{H_1 \times H_1 \times \dots \times H_1}_{m\text{-times}}$ , then the norm of an element  $f = (f_1, f_2, \dots, f_m) \in H_1^m$ , denoted by the same symbol as in  $H_1$  is given by

$$\|f\|_1 = \sum_{i=1}^m \|f_i\|_1.$$

The Banach space  $H_1^m$  is embedded in  $H^m$  in the sense that if  $f \in H_1^m$ , then  $f \in H^m$  and  $\|f\| \leq \|f\|_1$ .

The Hilbert space  $H_2(\Delta)$  of holomorphic functions in the open unit disc  $\Delta = \{z: |z| < 1\}$  is a realization of the abstract Hilbert space  $H$  and the product space  $H_2(\Delta)^m = \underbrace{H_2(\Delta) \times \cdots \times H_2(\Delta)}_{m\text{-times}}$  is a realization of the abstract Hilbert space  $H^m$ .

Similarly, the Banach space  $H_1(\Delta)$  of holomorphic functions having absolutely convergent power series expansions in the closed unit disc  $\bar{\Delta} = \{z: |z| \leq 1\}$ , is a realization of the abstract Banach space  $H_1$  and also,  $H_1(\Delta)^m = \underbrace{H_1(\Delta) \times \cdots \times H_1(\Delta)}_{m\text{-times}}$  is a realization of the space  $H_1^m$ .

It was shown in [5] that if  $a(z) = \sum_{n=1}^{\infty} a_n z^{n-1}$  is a holomorphic function in some neighborhood of the closed unit disc, then the linear scalar Briot-Bouquet differential equation

$$z \frac{df(z)}{dz} = a(z) f(z) \tag{2.1}$$

in the space  $H_2(\Delta)$  is equivalent to an abstract operator equation in  $H$  of the form

$$(C_0 - I) f = a^*(V) f, \tag{2.2}$$

where  $I$  is the identity operator,  $C_0$  is the diagonal operator defined above and  $a^*(V)$  is a bounded operator on  $H$  defined by the relation

$$a^*(V) = \sum_{n=1}^{\infty} \bar{a}_n V^{n-1}, \quad V^0 = I. \tag{2.3}$$

In (2.3)  $V$  is the unilateral shift operator on  $H$ , such that  $Ve_n = e_{n+1}$ ,  $n = 1, 2, \dots$  and  $\bar{a}_n$  is the complex conjugate of the coefficients of the function  $a(z)$ . Every function  $f(z) \in H_2(\Delta)$  is represented by

$$f(z) = (f_z, f),$$

where  $f \in H$  and  $f_z = \sum_{n=1}^{\infty} z^{n-1} e_n$  are the eigenelements of the operator  $V^*$ , the adjoint of  $V$ , which is defined by  $V^* : V^* e_n = e_{n-1}$ ,  $n \neq 1$ ,  $V^* e_1 = 0$ .

If  $a(z) \in H_1(\Delta)$ , then  $a^*(V)$  is a bounded operator on  $H_1$  and in addition,

$$\|a^*(V)\|_1 = \|a(z)\|_{H_1(\Delta)} = \sum_{n=1}^{\infty} |a_n|.$$

Moreover the operators  $V$ ,  $V^*$  and  $C_0$  fulfill the following properties:

- (i) The space  $H_1$  is invariant under  $V$ ,  $V^*$  and  $\|V\|_1 = \|V^*\|_1 = 1$ .
- (ii) If  $V^*$  is restricted to any subspace  $H - \{e_1, e_2, \dots, e_{n+1}\}$ , then  $V^*e_{n+2} = 0$ .
- (iii) Since  $V^*V = I$  and  $(C_0 - I)e_1 = 0$ , we have that  $VC_0V^* = C_0 - I$  and  $(C_0 - I)^k = VC_0^kV^*$ . (See ref. [4]).

Therefore, the differential equation (2.1) in the space  $H_1(\Delta)$  is equivalent to the abstract equation (2.2) in  $H_1$ , or equivalently the differential equation (2.1) is the realization of the operator equation (2.2).

By applying the operator  $B$  on the left in (2.2) we get

$$(I - B)f = Ba^*(V)f. \tag{2.4}$$

In a similar manner if  $A(z) = (a_{ij}(z))$ ,  $i, j = 1, 2, \dots, m$  is a matrix consisting of elements belonging to  $H_1(\Delta)$ , then the homogeneous vector Briot-Bouquet differential equation

$$z \frac{df(z)}{dz} = A(z)f(z), \tag{2.5}$$

where  $f(z) = (f_1(z), f_2(z), \dots, f_m(z))$ , is equivalent to the abstract equation

$$(\bar{C}_0 - I)f = \bar{A}(V)f$$

or

$$(I - \bar{B})f = \bar{B}\bar{A}(V)f, \tag{2.6}$$

where  $\bar{C}_0$  and  $\bar{B}$  are the operators defined above and  $\bar{A}(V)$  is given by the relation

$$\bar{A}(V)f = g, \text{ where } g = (g_1, g_2, \dots, g_m) \text{ with } g_i = \sum_{j=1}^m a_{ij}^*(V)f_j, \quad i = 1, 2, \dots, m.$$

### 3. Main results

We begin this section by proving some interesting and useful results about the operators  $\bar{C}_0$  and  $\bar{A}(V)$  in the abstract spaces  $H^m$  and  $H_1^m$ .

Let  $A(z)$  be given by  $A(z) = A(0) + zA_1(z)$ , with  $A(0)$  being the constant matrix,  $A(0) = \{a_{ij}(0)\}$ ,  $i, j = 1, 2, \dots, m$ , then its abstract equivalent is

$$\bar{A}(V) = \bar{A}(0) + V\bar{A}_1(V), \tag{3.1}$$

where  $\bar{A}(0)$  and  $V$  are defined on  $H^m$  or on  $H_1^m$  by the relations

$$Vf = (Vf_1, Vf_2, \dots, Vf_m)$$

and

$$\bar{A}(0)f = (g_i), \quad g_i = \sum_{j=1}^m \bar{a}_{ij}(0)f_j, \quad i = 1, 2, \dots, m.$$

**Lemma 3.1.** Let  $k \geq 1$  be an integer and consider the operator

$$(\bar{C}_0 - I)^k - \bar{A}(0). \tag{3.2}$$

A necessary and sufficient condition for its kernel to be nontrivial in  $H^m$  or in  $H_1^m$  is that at least one of  $0, 1, 2^k, 3^k, \dots$ , to be an eigenvalue of the constant matrix  $A(0)$ .

**Proof.** Assume that  $\lambda^k$ ,  $\lambda = 0, 1, 2, \dots$  is an eigenvalue of the constant matrix  $A(0)$  and  $\zeta = (\zeta_1, \zeta_2, \dots, \zeta_m)$  be a corresponding to it eigenvector.

Then the elements  $\zeta_q = (\bar{\zeta}_1 q, \bar{\zeta}_2 q, \dots, \bar{\zeta}_m q)$ ,  $q \in H(H_1)$  are eigenelements of the operator  $\bar{A}(0)$  in  $H^m(H_1^m)$ , which correspond to the eigenvalue  $\lambda^k$ . In particular,  $f_0 = (\bar{\zeta}_1 e_{\lambda+1}, \bar{\zeta}_2 e_{\lambda+1}, \dots, \bar{\zeta}_m e_{\lambda+1})$  is an eigenelement of the operator  $\bar{A}(0)$  in  $H_1^m$  corresponding to the eigenvalue  $\lambda^k$ .

Furthermore,  $f_0$  is also an eigenelement of the operator  $(\bar{C}_0 - I)^k$  in  $H_1^m$  corresponding to  $\lambda^k$ , which means that

$$[(\bar{C}_0 - I)^k - \bar{A}(0)]f_0 = 0$$

and therefore the kernel of the operator (3.2) is not trivial.

Conversely, assume that the kernel of the operator (3.2) is not trivial. Then there exists an  $f = (f_1, f_2, \dots, f_m) \neq 0$  in  $H_1^m$ , such that

$$[(\bar{C}_0 - I)^k - \bar{A}(0)]f = 0. \tag{3.4}$$

or

$$\begin{aligned} (C_0 - I)^k f_1 &= \bar{a}_{11}(0) f_1 + \bar{a}_{12}(0) f_2 + \dots + \bar{a}_{1m}(0) f_m \\ (C_0 - I)^k f_2 &= \bar{a}_{21}(0) f_1 + \bar{a}_{22}(0) f_2 + \dots + \bar{a}_{2m}(0) f_m \\ &\dots \dots \dots \\ &\dots \dots \dots \\ (C_0 - I)^k f_m &= \bar{a}_{m1}(0) f_1 + \bar{a}_{m2}(0) f_2 + \dots + \bar{a}_{mm}(0) f_m \end{aligned}$$

Taking scalar product of the above by  $e_n$ , we have that  $(C_0 - I)e_n = (n-1)e_n$  and thus for every  $n = 1, 2, \dots$  we get

$$\begin{aligned} (n-1)^k (e_n, f_1) &= \bar{a}_{11}(0)(e_n, f_1) + \bar{a}_{12}(0)(e_n, f_2) + \dots + \bar{a}_{1m}(0)(e_n, f_m) \\ (n-1)^k (e_n, f_2) &= \bar{a}_{21}(0)(e_n, f_1) + \bar{a}_{22}(0)(e_n, f_2) + \dots + \bar{a}_{2m}(0)(e_n, f_m) \\ &\dots \dots \dots \\ &\dots \dots \dots \\ (n-1)^k (e_n, f_m) &= \bar{a}_{m1}(0)(e_n, f_1) + \bar{a}_{m2}(0)(e_n, f_2) + \dots + \bar{a}_{mm}(0)(e_n, f_m) \end{aligned} \tag{3.5}$$

This implies that at least one of  $0, 1, 2^k, 3^k, \dots$  is an eigenvalue of the constant matrix  $A(0)$ , for otherwise,  $(e_n, f_i) = 0, \forall n = 1, 2, \dots$ , i.e.  $f_i = 0, i = 1, 2, \dots, m$ , which is a contradiction.

**Theorem 3.2.** Let  $A(0)$  be a constant matrix and  $f = (f_1, f_2, \dots, f_m) \neq 0$  be a solution of the operator equation

$$(\bar{C}_0 - I)^k f = \bar{A}(0) f. \tag{3.6}$$

Assume also that for some  $n = 1, 2, \dots$ , at least one of  $(e_n, f_1), (e_n, f_2), \dots, (e_n, f_m)$  is not equal to zero, then

$$(n-1)^k \leq \|A(0)\|. \tag{3.7}$$

**Proof.** For a nonzero element  $u_n = ((e_n, f_1), (e_n, f_2), \dots, (e_n, f_m)) \in H_1^m$  from (3.5) we have that

$$A(0)u_n = (n-1)^k u_n \tag{3.8}$$

or  $\|A(0)u_n\|_1 = (n-1)^k \|u_n\|_1$  and since  $n \geq 1$ ,  $\|A(0)u_n\|_1 = (n-1)^k \|u_n\|_1$ .

Hence (3.7) follows from the fact that (see [6])

$$\|A(0)\| = \sup_{u_n \neq 0} \frac{\|A(0)u_n\|_1}{\|u_n\|_1}.$$

For  $k=1$ , (3.7) implies that  $n-1 \leq \|A(0)\|$ , which means that  $(e_n, f_i) = 0$ ,  $i=1,2,\dots,m$  for every  $n > \|A(0)\| + 1$ . Therefore we obtain the following result concerning the vector Briot-Bouquet differential equation.

**Theorem 3.3.** Assume that there exists a function  $f(z) = (f_1(z), f_2(z), \dots, f_m(z))$  in  $H_2(\Delta)^m$ , satisfying the vector Briot-Bouquet differential equation

$$z \frac{df(z)}{dz} = Af(z), \tag{3.9}$$

where  $A$  is any constant matrix, then the components of  $f(z)$  are polynomials of degree less or equal to  $1 + \|A\|$ .

Moreover if  $A$  is a nonsingular matrix such that  $1 > \|A\|$ , then the vector differential equation (3.9) has no solutions in  $H_2(\Delta)^m$ .

Now consider the subspace  $M(\lambda)$  of  $H^m$ , which is spanned by the  $m(\lambda+1)$  elements  $e_{ni}$ ,  $n=1,2,\dots,(\lambda+1)$ ,  $i=1,2,\dots,m$  and denote by  $M^c(\lambda)$  its orthogonal complement. Furthermore, let  $M_1(\lambda)$  be the intersection

$$M_1(\lambda) = M^c(\lambda) \cap H_1^m.$$

Clearly, this is a Banach space, which is invariant under the operators  $\bar{B}$  and  $\bar{A}(V)$ .

**Lemma 3.4.** Assume that  $\lambda^k$  is the greatest, positive eigenvalue of the matrix  $A(0)$ , then the bounded operator

$$(I - \bar{B})^k - \bar{A}(V)\bar{B}^k, \tag{3.10}$$

when restricted to the subspace  $M_1(\lambda)$  of  $H_1^m$ , possesses a bounded inverse.

**Proof.** By lemma 3 of theorem 3.2 in [5], it can be seen that  $\bar{B}^k$  is a compact operator on  $M_1(\lambda)$  and since  $\bar{A}(V)$  is bounded, the operator (3.10) is of the form  $I - K$ , where  $K$  is a compact operator on  $M_1(\lambda)$ .

Therefore, by the Fredholm alternative, (3.10) is invertible if the kernel of  $I - K$  is trivial.

On the other hand if  $g \neq 0$  is an element of the kernel of the operator (3.10) in  $M_1(\lambda)$ , then by setting  $g = \bar{C}_0^k f$ , i.e.  $f = \bar{B}^k g$  in the equation

$$\left( (I - \bar{B})^k - \bar{A}(V)\bar{B}^k \right) g = 0$$

we get

$$(\bar{C}_0 - I)^k f = \bar{A}(V)f. \tag{3.11}$$

Since  $M_1(\lambda)$  is invariant under  $\bar{B}$  and  $g \in M_1(\lambda)$  it is implied that  $f$  is also an element of the subspace  $M_1(\lambda)$ , thus

$$(f_i, e_1) = (f_i, e_2) = \dots = (f_i, e_{\lambda+1}) = 0, \quad i = 1, 2, \dots, m$$

and

$$(a_{ij}^*(V) f_j, e_{\lambda+2}) = \bar{a}_{ij}(0)(f_j, e_{\lambda+2}), \quad i, j = 1, 2, \dots, m. \tag{3.12}$$

Taking scalar product multiplication of the components of (3.11) by  $e_{\lambda+2}$  we obtain

$$\begin{aligned} (\lambda + 1)^k (e_{\lambda+2}, f_1) &= \bar{a}_{11}(0)(e_{\lambda+2}, f_1) + \bar{a}_{12}(0)(e_{\lambda+2}, f_2) + \dots + \bar{a}_{1m}(0)(e_{\lambda+2}, f_m) \\ (\lambda + 1)^k (e_{\lambda+2}, f_2) &= \bar{a}_{21}(0)(e_{\lambda+2}, f_1) + \bar{a}_{22}(0)(e_{\lambda+2}, f_2) + \dots + \bar{a}_{2m}(0)(e_{\lambda+2}, f_m) \\ &\dots \dots \dots \tag{3.13} \\ &\dots \dots \dots \end{aligned}$$

$$(\lambda + 1)^k (e_{\lambda+2}, f_m) = \bar{a}_{m1}(0)(e_{\lambda+2}, f_1) + \bar{a}_{m2}(0)(e_{\lambda+2}, f_2) + \dots + \bar{a}_{mm}(0)(e_{\lambda+2}, f_m)$$

Now, since  $\lambda^k$  is the greatest positive integer eigenvalue of  $A(0)$  and  $V^* e_{n+2} = 0$  when restricted to  $H - \{e_1, e_2, \dots, e_{\lambda+1}\}$ , it is implied by (3.13) that  $(e_{\lambda+2}, f_i) = 0$ ,  $i = 1, 2, \dots, m$ .

Continuing in this same way we obtain  $(e_{\lambda+3}, f_i) = 0$ ,  $i = 1, 2, \dots, m$  and so on. Thus  $f = 0$ .

We note here that in case the constant matrix  $A(0) = 0$ , the above lemma is true for the operator

$$(I - \bar{B}) - V\bar{A}_1(V)\bar{B},$$

for every positive integer  $\lambda^k$ .

Following the proof of lemma 3.4 above it can be shown that the operator

$$(\bar{C}_0 - I)^k - \bar{A}(V) \tag{3.14}$$

has a bounded inverse in  $H^m$ , as well as in  $H_1^m$ , on the condition that the non-zero constant matrix  $A(0)$  possesses eigenvalues different from  $0, 1, 2^k, 3^k, \dots$

More precisely, since the operator (3.14) is of the form  $\bar{C}_0^k (I - K)$ , where  $K$  is a compact operator, it is sufficient to show, as in lemma 3.1, that its kernel is trivial.

To that end let

$$(\bar{C}_0 - I)^k f = \bar{A}(V) f, \tag{3.15}$$

from which, taking scalar product by  $e_1$ , we have

$$\begin{aligned} 0 &= \bar{a}_{11}(0)(e_1, f_1) + \bar{a}_{12}(0)(e_1, f_2) + \dots + \bar{a}_{1m}(0)(e_1, f_m) \\ 0 &= \bar{a}_{21}(0)(e_1, f_1) + \bar{a}_{22}(0)(e_1, f_2) + \dots + \bar{a}_{2m}(0)(e_1, f_m) \\ &\dots \tag{3.16} \\ &\dots \\ 0 &= \bar{a}_{m1}(0)(e_1, f_1) + \bar{a}_{m2}(0)(e_1, f_2) + \dots + \bar{a}_{mm}(0)(e_1, f_m) \end{aligned}$$

Since 0 is not an eigenvalue of  $A(0)$ , it follows that  $(e_1, f_i) = 0, i = 1, 2, \dots, m$  and hence we get, by scalar multiplication of (3.15) by  $e_2$

$$\begin{aligned} (e_2, f_1) &= \bar{a}_{11}(0)(e_2, f_1) + \bar{a}_{12}(0)(e_2, f_2) + \dots + \bar{a}_{1m}(0)(e_2, f_m) \\ (e_2, f_2) &= \bar{a}_{21}(0)(e_2, f_1) + \bar{a}_{22}(0)(e_2, f_2) + \dots + \bar{a}_{2m}(0)(e_2, f_m) \\ &\dots \\ &\dots \\ (e_2, f_m) &= \bar{a}_{m1}(0)(e_2, f_1) + \bar{a}_{m2}(0)(e_2, f_2) + \dots + \bar{a}_{mm}(0)(e_2, f_m) \end{aligned}$$

Since 1 is not an eigenvalue of  $A(0)$ , it follows that  $(e_2, f_i) = 0, i = 1, 2, \dots, m$ .

Repeating this process we find  $(e_3, f_i) = (e_4, f_i) = \dots = 0, i = 1, 2, \dots, m$ .

Therefore  $f = 0$  and the operator (3.14) has a bounded inverse. Hence we have proved the following.

**Theorem 3.5.** The non-homogeneous abstract equation

$$\left[ (\bar{C}_0 - I)^k - \bar{A}(V) \right] f = g \tag{3.17}$$

possesses a unique solution in  $H^m(H_1^m)$  for every  $g \in H^m(H_1^m)$ . This solution has the form

$$f = (I - K)^{-1} \bar{B}^k g,$$

where  $K$  is a compact operator.

Following theorem 3.3 of ref. [5], it can be shown that the range of the operator  $\bar{B}^k$  in  $H^m(H_1^m)$  is invariant under the operator  $(I - K)^{-1}$ , which means that if  $g \in H^m(H_1^m)$ , then the solution of the differential equation that realizes the abstract equation (3.17) in  $H(\Delta)^m$ , together with its derivatives up to order  $k-1$  belong to  $H_1(\Delta)^m$ .

The following result provides even more information about the form of the solution of the equation (3.17).

**Theorem 3.6.** Let the constant matrix  $A(0)$  possess eigenvalues different from  $0, 1, 2^k, 3^k, \dots$ . Then for every  $g$  in  $H^m$  there exists a constant vector  $\mu = (\mu_1, \mu_2, \dots, \mu_m)$  and an element  $q = (q_1, q_2, \dots, q_m) \in H^m$  such that the unique solution of the abstract equation (3.17) is given by

$$f = \mu_0 + \bar{B}^k q, \quad (q_i, e_i) = 0, \quad i = 1, 2, \dots, m, \tag{3.18}$$

where  $\mu_0 = (\bar{\mu}_1 e_1, \bar{\mu}_2 e_1, \dots, \bar{\mu}_m e_1) \in H_1^m$ .

**Proof.** Inserting (3.18) into (3.17) we get

$$(I - \bar{B})^k q - \bar{A}(V) \mu_0 - \bar{A}(V) \bar{B}^k q = g$$

or equivalently, by the relation (3.1) we have

$$(I - \bar{B})^k q - [\bar{A}(0) + V\bar{A}_1(V)] \mu_0 - \bar{A}(V) \bar{B}^k q = g. \tag{3.19}$$

Denote by  $\mu_1$  the element  $\mu_1 = ((g_1, e_1)e_1, (g_2, e_1)e_1, \dots, (g_m, e_1)e_1)$ , where  $g_i, i = 1, 2, \dots, m$  are the components of the function  $g$ . The fact that the matrix  $A(0)$  is non-singular, implies that a constant vector  $\mu = (\mu_1, \mu_2, \dots, \mu_m)$  can be found for which  $\bar{A}(0) \mu_0 = -\mu_1$ . Hence, from (3.19) we get

$$\left[ (I - \bar{B})^k - \bar{A}(V) \bar{B}^k \right] q = g - \mu_1 + V\bar{A}_1(V) \mu_0. \tag{3.20}$$

Let  $w_i, i = 1, 2, \dots, m$  be the components of the element

$$w = g - \mu_1 + V\bar{A}_1(V)\mu_0.$$

They obviously satisfy the condition  $(w_i, e_i) = 0, i = 1, 2, \dots, m$ , which means that  $w$  belongs to the subspace  $H^m - \{e_i, i = 1, 2, \dots, m\}$ , which is invariant under the operators  $(I - \bar{B})^k$  and  $\bar{A}(V)\bar{B}^k$ . Also by lemma 3.4, the operator

$$(I - \bar{B})^k - \bar{A}(V)\bar{B}^k,$$

when restricted to that subspace, has a bounded inverse, i.e. equation (3.17) has a unique solution of the form (3.18).

Next we consider the case in which the elements of the matrix  $A(z)$  are holomorphic functions in the closed unit disc and thus the operator  $a_{ij}^*(V)$  is bounded on  $H$ , whereas the operator  $\bar{A}(V)$  is bounded on  $H^m$ .

We proceed by proving the existence of a holomorphic solution for first and second order non-homogeneous vector differential equations, but these results can be readily extended to equations of higher order due to theorems 3.5 and 3.6.

**Theorem 3.7.** Consider the non-homogeneous vector differential equation

$$z \frac{df(z)}{dz} - A(z)f(z) = g(z), \tag{3.21}$$

where  $g(z) = (g_1(z), g_2(z), \dots, g_m(z)) \in H_2(\Delta)^m$  and the constant matrix  $A(0)$ , has eigenvalues different from  $0, 1, 2, \dots$ . Then there exists a vector-valued solution of (3.21),  $f(z) = (f_1(z), f_2(z), \dots, f_m(z))$  having the form

$$f_i(z) = \mu_i + \sum_{n=1}^{\infty} b_{in}z^n, \quad i = 1, 2, \dots, m, \tag{3.22}$$

where the vector  $\mu = (\mu_1, \mu_2, \dots, \mu_m)$  is the unique solution of the system  $A(0)\mu = (g_1(0), g_2(0), \dots, g_m(0))$ . Moreover the series (3.22) is absolutely convergent in the closed unit disc and if  $g(z) \in H_1(\Delta)^m$ , then the first order derivatives  $\frac{df_i(z)}{dz}, i = 1, 2, \dots, m$  are also absolutely convergent.

**Proof.** The differential equation (3.21) is equivalent to the operator equation

$$\left[ (\bar{C}_0 - I) - \bar{A}(V) \right] f = g, \tag{3.23}$$

where  $g_i(z) = (f_z, g_i)$ ,  $i = 1, 2, \dots, m$ .

Theorems 3.5 and 3.6 imply that the abstract equation (3.23) possesses a unique solution in the space  $H^m$  of the form  $f = \mu_0 + \bar{B}q$ , which is the realization of an element of the form (3.22) in the space  $H_2(\Delta)^m$ .

In the case where  $q$  belongs to  $H_1^m$ , we have that  $\bar{B}q \in H_1^m$  and so the series (3.22) converges absolutely in  $\bar{\Delta} = \{z : |z| \leq 1\}$ . Moreover, since the space  $H_1(\Delta)^m$  remains invariant under the operator  $\bar{B}$ ,  $f = \mu_0 + \bar{B}q$  is an element of the definition domain of  $\bar{C}_0$  in  $H_1^m$ . This means that the first order derivatives of (3.22) converge absolutely in  $\bar{\Delta}$ .

**Theorem 3.8.** Consider the second order vector differential equation

$$z^2 \frac{d^2 f(z)}{dz^2} + z \frac{df(z)}{dz} = A(z) f(z) + g(z), \tag{3.24}$$

where  $g(z) = (g_1(z), g_2(z), \dots, g_m(z))$  is an element of  $H_2(\Delta)^m (H_1(\Delta)^m)$  and the constant matrix  $A(0)$  has eigenvalues different from  $0, 1, 2^2, 3^2, \dots$ .

Then there exists a vector-valued solution of (3.24) of the form (3.22), which together with its derivatives up to order one (two) converge absolutely in the closed unit disc.

**Proof.** The product  $z^2 \frac{d^2 f(z)}{dz^2}$ , when  $f(z)$  is a function in  $H_2(\Delta)(H_1(\Delta))$ , is equivalent to  $V^2(C_0V^*)^2 f$  in  $H_2(H_1)$ , [4].

Also, as we have seen  $z \frac{df(z)}{dz}$  is equivalent to  $VC_0V^* f$  or  $(C_0 - I) f$ .

It follows that the left hand side of the given vector differential equation (3.24) in  $H_2(\Delta)^m (H_1(\Delta)^m)$ , is equivalent in  $H^m(H_1^m)$  to

$$V^2(\bar{C}_0V^*)^2 f + VC_0V^* f$$

or

$$\begin{aligned}
V^2 \bar{C}_0 V^* \bar{C}_0 V^* f + V \bar{C}_0 V^* f &= V (\bar{C}_0 - I) \bar{C}_0 V^* f + V \bar{C}_0 V^* f \\
&= V \bar{C}_0^2 V^* f \\
&= (\bar{C}_0 - I)^2 f
\end{aligned}$$

Hence, the equivalent operator equation of (3.24) is given by

$$(\bar{C}_0 - I)^2 f = \bar{A}(V) f + g. \quad (3.25)$$

By theorems 3.5 and 3.6 there exists a unique solution of (3.25) of the form  $f = \mu_0 + \bar{B}^2 q$ , which belongs to the definition domain of  $\bar{C}_0$  in  $H_1^m$ , for  $q \in H_1^m$  and to the definition domain of  $\bar{C}_0^2$  in  $H_1^m$ , for  $q \in H_1^m$ . Hence the proof of theorem (3.8) follows.

Theorems 3.5 and 3.6 also predict the existence of entire solutions for the vector non-homogeneous differential equations (3.21) and (3.24) as the following corollaries show.

**Corollary 3.9.** Let the element  $a_{ij}(z)$ ,  $i, j = 1, 2, \dots, m$  of the matrix  $A(z)$  and the components  $g_i(z)$ ,  $i = 1, 2, \dots, m$  of  $g(z)$  be entire functions. If the conditions of theorem (3.7) are true, then the differential equation (3.21) possesses a unique entire solution  $f(z)$  whose components are given by (3.22).

**Corollary 3.10.** Let the element  $a_{ij}(z)$ ,  $i, j = 1, 2, \dots, m$  of the matrix  $A(z)$  and the components  $g_i(z)$ ,  $i = 1, 2, \dots, m$  of  $g(z)$  be entire functions. If the conditions of theorem (3.8) are true, then the differential equation (3.24) possesses a unique entire solution  $f(z)$  with components of the form (3.22).

The proofs of both the above corollaries follow easily if we use the transformation  $z = r\psi$  and thus obtain unique solutions  $f(r\psi)$  of (3.21) and (3.24) that are holomorphic in  $\Delta = \{\psi : |\psi| < 1\}$ , for every  $r > 0$ .
