Convergence of Lagrange Interpolation
on the Unit Circle

Abstract: In this paper, we study the convergence of Lagrange interpolation polynomials on the sets obtained by projecting vertically the zeros of \((1 - x^2) P_n(x)\) onto the unit circle, where \(P_n(x)\) stands for \(n^{th}\) Legendre polynomial.

Mathematics Subject Classification: 41A05, 30E10

Keywords: Legendre polynomial, Lagrange interpolation, convergence

1. Introduction:

In a paper, P. Nevai [6] considered the necessary and sufficient conditions for convergence of Lagrange interpolation based at the zeros of generalized Jacobi polynomials in Lp spaces with general weights. In 1994, Xin Li and E.B. Saff [3] considered the function \(f\) which is bounded on \([-1, 1]\) and analytic at \(x = 0\) and proved the local convergence of Lagrange interpolating polynomials of \(f\) associated with equidistant nodes on \([-1, 1]\). In 1997, F. Peherstarfer [7] have studied the convergence of Lagrange interpolation on the triangular matrix \(X\) given by \(-1 < x_{1,n} < x_{2,n} < \ldots < x_{n,n} < 1, n = 1, 2, \ldots\).

After that, D.S. Lubinsky [4] obtained the necessary and sufficient condition for the mean convergence of the Lagrange interpolation at the zeros of orthogonal polynomials for weights on \([-1, 1]\). In another paper [5], he considered the mean convergence of Lagrange interpolating polynomial. Later on S.B. Damelin, H.S. Jung and K.H. Kwan [2] considered the mean convergence of Lagrange interpolation for weights in \(L_p (0 < p < 1)\).

In the case of complex plane, R. Brück [1] have studied the convergence of Lagrange interpolation of a function on the nodes \(z_{kn}^{\alpha} = T_{\alpha} (\omega_{kn}), k = \ldots\)
1 (1) 2n where $T_\alpha$ is a Möbius transform of a unit disk into itself and $\omega_{kn} = \exp \left( \frac{2\pi ik}{3n+1} \right), n \geq 0$. Recently Xie Siqing [9] considered weighted least square convergence of Lagrange interpolation polynomials based on the sets obtained by projecting vertically the zeros of

\[(1 - x^2) P_n^{(\alpha, \beta)} (x) (\alpha > 0, \beta > 0), (1 + x) P_n^{(\alpha, \beta)} (x) (\alpha > -1, \beta > 0), (1 - x) P_n^{(\alpha, \beta)} (x) (\alpha > 0, \beta > -1) \text{ and } P_n^{(\alpha, \beta)} (x) (\alpha > -1, \beta > -1), \text{ respectively onto the unit circle, where } P_n^{(\alpha, \beta)} (x) (\alpha > -1, \beta > -1) \text{ stands for the } n^{th} \text{ Jacobi polynomial.}

The Problem:

In this paper, we have considered the convergence of Lagrange interpolation polynomials on the nodes obtained by projecting vertically the zeros of

\[(1 - x^2) P_n (x) \text{ onto the unit circle, where } P_n (x) \text{ stands for the } n^{th} \text{ Legendre polynomial.}

Let

\[Z_n = \{z_0 = 1, z_{2n+1} = -1, z_k = \cos \theta_k + i \sin \theta_k, z_{n+k} = -z_k, \ k = 1 (1) n\}

be the zeros of

\[R(z) = (z^2 - 1) W(z)

where

\[W(z) = \prod_{k=1}^{2n} (z - z_k) = K_n P_n (x) z^n

Then $Z_n$ denotes the vertical projections on the unit circle of the zeros of

\[(1 - x^2) P_n (x). \text{ The object of this paper is to obtain a quantitative estimate of } |L_n(z) - f(z)|, \text{ where } L_n(z) \text{ is the Lagrange interpolation polynomial of degree } \leq 2n + 1. \text{ Then}

\[L_n(z) = \sum_{k=0}^{2n+1} f(z_k) l_k(z)

where

\[l_k(z) = \frac{R(z)}{R(z_k)(z-z_k)}

such that

\[l_k(z_j) = \delta_{kj} = \begin{cases} 0, & k \neq j, \\ 1, & k = j, \end{cases} \text{ for } j, k = 0 (1) 2n + 1.

2. Main Result:

Let $\lambda_n$ be the Lebesgue constant for $l_k$ i.e.

\[\lambda_n = \max \lambda_n (z) \text{ for } |z| \leq 1

where

\[(2.2) \quad \lambda_n (z) = \sum_{k=0}^{2n+1} |l_k (z)|.\]

**Lemma 1:**[8, 694 – 695]

\[(2.3) \quad \lambda_n \leq c_1 \log n + c_2,\]

where \(c_1\) and \(c_2\) are constants.

**Theorem:** Let \(f(z)\) be continuous in \(|z| \leq 1\) and analytic in \(|z| < 1\), then the sequence of interpolatory polynomial \(\{ L_n \}\) defined by (1.4) satisfies the relation

\[(2.4) \quad |L_n (z) - f(z)| = o(1).\]

**Remark:** To prove the theorem, we need Jackson’s theorem:

Let \(f(z)\) be continuous in \(|z| \leq 1\) and analytic in \(|z| < 1\), then there exists a polynomial \(F_n (z)\) of degree \(\leq 2n + 1\) such that

\[(2.5) \quad |F_n (z) - f(z)| \leq c \omega (f, \frac{1}{n}), \quad z = e^{i\theta}, \quad (0 \leq \theta < 2\pi),\]

where \(\omega (f, \delta)\) is the modulus of smoothness of \(f(z)\).

**Proof:** Since \(L_n (z)\) is the uniquely determined polynomial of degree \(\leq 2n + 1\) given by (1.4), therefore, the polynomial \(F_n(z)\) satisfying (2.5) can be expressed as:

\[F_n(z) = \sum_{k=0}^{2n+1} F_n (z_k) l_k (z).\]

Then

\[|L_n (z) - f(z)| \leq |L_n (z) - F_n (z)| + |F_n (z) - f(z)|\]

Taking \(z = e^{i\theta}, \quad (0 \leq \theta < 2\pi)\) and using (2.3) and (2.5), we get (2.4), which completes the proof of the theorem.
