On the Generators of Codes of Ideals of the Polynomial Ring $F_2^N [X] / \langle X^N - 1 \rangle$
for Error Control

Abstract

Shannon introduced error detection and correction codes to address the growing need of efficiency and reliability of code vectors. One of the structures that can generate these codes is a set of ideals of the candidate polynomial ring. Generators of codes of ideals of polynomial rings have not been fully characterized. In this research the generators of codes of the candidate polynomial ring $F_2^N [x]/\langle x^n - 1 \rangle$ have been investigated and characterized using lattices, simplex Hamming codes and isometries.

Mathematics Subject Classification: Primary 20K30; Secondary 16P10

Keywords: Polynomial Ring, Ideals, generators of codes, Error Control

1 Introduction

1.1 Background information

Definition 1.1. [5] Let $A$ be a finite set. A code is a non-empty subset of the set $A^n$ of $n$-tuples of elements from $A$. Let $C$ be a code constructed by elements of $A$. If $C$ is a code of length $n$ and size $|C|$, then $C$ is an $(n, |C|)$ code.
Members of the code space are words, those belonging to $C$ being codewords. If $A$ has $m$ elements, then $C$ is said to be an $m$-ary code. If $|A|=2$, then $C$ is a binary code and the set $A=\{0,1\}$.

1.2 Types of Computer Errors

According to Williams [9] in digital transmission systems, an error occurs when a bit is altered between transmission and reception, that is a binary 1 is transmitted and a binary 0 is received or a binary 0 is transmitted and a binary 1 is received. Two general types of errors can occur; single bit (random) errors and burst (compound) errors. A single bit error is an isolated error condition that alters one bit but does not affect nearby bits. A burst error of length $b$ is a continuous sequence of $b$ - bits in which the first and the last bits and any number of intermediate bits are received in error.

1.3 Error detection, correction and control

Definition 1.2. [4] Error detection is the ability to identify presence of errors caused by noise or other impairments during transmission from the transmitter to the receiver.

Error correction is the ability to reconstruct the original, error free data.

Error control is the ability to detect and correct errors using a given code.

The tools we have used to characterize our results include kissing numbers, lattices and isometries.

Definition 1.3. Wheeler [8] Kissing number is the number of $n$- spheres which can be arranged so that they all touch another central sphere of the same size. It is given by:

$$T(\Lambda) = |\{ x \in \Lambda : \|x\| = d_{\text{min}}(\Lambda) \}|.$$

A kissing number determines the maximum number of nearest neighbors a given code is likely to have. In error control coding a higher kissing number means a code has very many useful neighbors and can be easily decoded using minimum distance decoding.

According to Wheeler [8] the hyper volume and hyper surface area of sphere packing reduces significantly as $n$ increases. Thus for the candidate polynomial ring $F_2^n[x]/\langle x^n - 1 \rangle$, we have $\lim_{n \to \infty}\text{hyper surface area} \to 0$ and $\lim_{n \to \infty}\text{hyper volume} \to 0$. In such a case the kissing numbers become very large. Hence too much kissing goes on as $n$ approaches infinity. Therefore as $n \to \infty$, we are bound to get better codes for the purpose of error control.
1.4 Ideals in a commutative ring

Definition 1.4. [6]
A non-empty subset $I$ of a ring $F_2^n[x]/\langle x^n - 1 \rangle$ is an ideal of $F_2^n[x]/\langle x^n - 1 \rangle$ if and only if:

(i) $0 \in I$
(ii) $\forall a, b \in I, a \pm b \in I$
(iii) $\forall a \in I$ and $r \in F_2^n[x]/\langle x^n - 1 \rangle$, $ra \in I$.

The ring $F_2^n[x]/\langle x^n - 1 \rangle$ itself and the subset consisting of 0 alone, denoted by $\{0\}$, are ideals in this ring called trivial or improper ideals. An ideal $I \neq F_2^n[x]/\langle x^n - 1 \rangle$ is a proper ideal (see Olege, et al. [2]).

Since $F_2^n[x]/\langle x^n - 1 \rangle$ is commutative then $ar = ra$. An ideal $I$ has closure if $a \pm b \in I$, for all $a, b \in I$. An ideal $I$ absorbs elements from $F_2^n[x]/\langle x^n - 1 \rangle$, if $ra, ar \in I$ for all $a \in I$ and for all $r \in F_2^n[x]/\langle x^n - 1 \rangle$.

The left principal ideal of a ring $R$ is a subset of $R$ of the form $RI = \{aI : a \in R\}$. The right principal ideal of a ring $R$ is a subset of the form $IR = \{Ia : a \in R\}$. A two-sided principal ideal is a subset of the form $RIR = \{aIa : a \in R\}$. In a commutative ring, these three types of ideals coincide.

2 Results

Theorem 2.1. Let $g(x) \in F_2^n[x]/\langle x^n - 1 \rangle$ be an irreducible and monic factor of $x^n - 1$. The following statements are equivalent:

(i) $g(x)$ is a generator polynomial of $F_2^n[x]/\langle x^n - 1 \rangle$.
(ii) $\langle g(x) \rangle$ is a generator of the set of ideals $I(C) \in F_2^n[x]/\langle x^n - 1 \rangle$.

Proof
(i) $\Rightarrow$ (ii). Suppose $g(x)$ is a generator polynomial of $F_2^n[x]/\langle x^n - 1 \rangle$ and is a factor of $x^n - 1$. Then $p(x)g(x) = x^n - 1$ for some $p(x) \in F_2^n[x]/\langle x^n - 1 \rangle$. Hence $\langle g(x) \rangle$ is a generator of the set of ideals $I(C) \in F_2^n[x]/\langle x^n - 1 \rangle$.

(ii) $\Rightarrow$ (i). Suppose that $\langle g(x) \rangle$ is a generator of the set of ideals $I(C) \in F_2^n[x]/\langle x^n - 1 \rangle$. Then any element of $I(C)$ would be given by $p(x)g(x)$ for some $p(x) \in F_2^n[x]/\langle x^n - 1 \rangle$. Hence there exists some $h(x) \in F_2^n[x]/\langle x^n - 1 \rangle$ such that any element of $I(C)$ is given by $p(x)h(x) = x^n - 1$. Hence $g(x)$ is the generator polynomial of $F_2^n[x]/\langle x^n - 1 \rangle$.

Proposition 2.1. For a given polynomial code $P_c \in F_2^n[x]/\langle x^n - 1 \rangle$ the generator polynomial $g(x)$ is unique.

Proof
Assume the polynomial code $P_c \in F_2^n[x]/\langle x^n - 1 \rangle$ has two generator polynomials $g(x)$ and $g(x)'$. Since $g(x)'$ is the other generator polynomial then
Let a polynomial \( g(x) \) be irreducible. Then the polynomial ring \( F_2^n [x] / \langle \sigma(x) \rangle \) is a field.

**Proof**

Let \( r(x) \) be a non-zero element of \( F_2^n [x] / \langle \sigma(x) \rangle \). If \( r(x) \) is co-prime to \( \sigma(x) \) then we can find polynomials \( \alpha(x) \) and \( \beta(x) \) such that \( r(x)\alpha(x) + \sigma(x)\beta(x) = 1 \). But \( r(x)\alpha(x) \equiv 1 \mod \sigma(x) \) implies that \( r(x) \) has a multiplicative inverse \( \alpha(x)/\sigma(x) \).

**Proposition 2.2.** A polynomial code \( P_c \in F_2^n [x] / \langle x^n - 1 \rangle \) can control up to \( e \) errors if and only if \( d_{\text{max}} \geq 2e + 1 \).

**Proof**

Suppose \( P_c \) cannot control up to \( e \) errors. Then there exists a pattern of at most \( e \) errors which changes the code vector \( u \) into a code vector \( v \) for all \( u, v \in P_c \). Since we can change \( u \) into \( v \) using a maximum of \( e \) errors, we have \( d_{\text{max}}(u, v) \leq e \). Suppose it was not possible to change \( v \) then we have a code vector \( w \neq u \) with \( d_{\text{max}}(w, v) \leq d_{\text{max}}(u, v) \) for some \( w \in P_c \). Hence \( d_{\text{max}}(w, v) \leq e \). By triangle inequality \( d_{\text{max}}(u, v) + d_{\text{max}}(v, w) \leq e + e = 2e \) which contradicts \( d_{\text{max}} \geq 2e + 1 \).

**Proposition 2.3.** A polynomial ring \( F_2^n [x] / \langle x^n - 1 \rangle \) generates an error control code for \( n \geq 3 \).

**Proof**

Assume the contrary that the polynomial ring \( F_2^n [x] / \langle x^n - 1 \rangle \) does not generate error control codes. Then \( F_2^n [x] / \langle x^n - 1 \rangle \) has a maximum Hamming distance \( d_{\text{max}} < 3 \) for all the codewords it generates. But the most optimal codeword generated by \( F_2^n [x] / \langle x^n - 1 \rangle \) has \( d_{\text{max}} = n \geq 3 \). This contradicts the original assumption. Hence \( F_2^n [x] / \langle x^n - 1 \rangle \) generates an error control code.

Suppose we want to show the maximum number of errors the code generated by \( F_2^{11} [x] / \langle x^{11} - 1 \rangle \) can control. Then;

\[
2e + 1 = d_{\text{max}} \quad \text{(where \( e \) is the maximum number of errors this code can control)}
\]

\[
\Rightarrow 2e + 1 = 11
\]

\[
\Rightarrow e = 5
\]

**Table 1: Generator Polynomials of \( F_2^{11} [x] / \langle x^{11} - 1 \rangle \)**
From Table 1 the codewords in $C$ are ideals of the polynomial ring $F_2^{11}[x]/\langle x^{11} − 1 \rangle$. Here $m = 4, n = 11$ (which is a safe prime), $W_{\text{max}} = 11$, $d_{\text{max}} = 11$, $(n, m, d_{\text{max}}) = (11, 4, 11)$.

By Proposition 2.2 this code can control up to five errors.

**Definition 2.1.** [7]

A lattice $\Lambda$ is a discrete additive subgroup of $\mathbb{R}^n$. That is $\Lambda \subseteq \mathbb{R}$ satisfying the following properties:

(i) $\Lambda$ is closed under addition and subtraction.

(ii) There exists an $\epsilon > 0$ such that any two distinct lattice points $x \neq y$ are at a distance at least $|x − y| \geq \epsilon$.

In order to study their lattice properties we shall treat polynomial codes as spheres. Let a packing $P \subset \mathbb{R}^n$ contain spheres centered at $u$ and $v$. Suppose this is true, then there is also a sphere centered at either $u + v$ or $u − v$.

**Claim 2.1.** We claim that the minimum Hamming distance $d_c$ induces a metric in the code space.

**Proposition 2.4.** Suppose $1 ≤ c < \infty$ and $d_c$ is the minimum Hamming distance of polynomial codes $u, v \in F_2^n[x]/\langle x^n − 1 \rangle$ given by $d_c(u, v) = (\sum_{i=1}^n | u_i − v_i |^c)^{1/c}$ for $u = (u_1, u_2, ..., u_n)$ and $v = (v_1, v_2, ..., v_n)$. Then, the induced metric in the code space is given by $d_c(u, v) = (\sum_{i=1}^n d(u_i, v_i)^c)^{1/c}$.

**Proof**

Suppose $u = (u_1, u_2, ..., u_n)$ and $v = (v_1, v_2, ..., v_n)$ for all $u, v \in F_2^n[x]/\langle x^n − 1 \rangle$. The metric induced by $d_c$ is given by $d_c(u, v) = \inf_{u'}d(u', v')$; where $u' = u + qe, v' = v + qz$ for all $e, z \in F_2^n[x]/\langle x^n − 1 \rangle = (\inf \{ \sum_{i=1}^n | u_i − v_i − q(z_i − e_i) |^c, e, z \in F_2^n[x]/\langle x^n − 1 \rangle \})^{1/c} = (\sum_{i=1}^n | u_i − v_i − q(\frac{u_i − v_i}{q}) |^c)^{1/c}$. (i)

Equation (i) is minimum when $= (\sum_{i=1}^n | u_i − v_i − qA_i |^c)^{1/c}$, for $A_i = | \frac{u_i − v_i}{q} |$.

Suppose $\alpha_i = \left( \frac{u_i - v_i}{q} \right)$ for $i = 1, 2, 3, \ldots, n$. Since $0 \leq |u_i - v_i| \leq q$, it follows that $-1 \leq \frac{u_i - v_i}{q} \leq 0$. If $\alpha_i \geq 0$ for some $i$ then $\frac{u_i - v_i}{q} \leq \frac{q}{2}$. In such a case $\min \{ |u_i - v_i|, q - |u_i - v_i| \} = |u_i - v_i|$. If $\alpha_i = 1$ for some $i$ then $\frac{u_i - v_i}{q} \leq u_i - v_i \leq q$ and $\min \{ |u_i - v_i|, q - |u_i - v_i| \} = q - |u_i - v_i|$. If $\alpha_i = -1$ for some $i$ then $-q \leq u_i - v_i \leq \frac{q}{2}$ and $\min \{ |u_i - v_i|, q - |u_i - v_i| \} = q - |u_i - v_i|$. Hence
\[ d_c(u, v) = \left( \sum_{i=1}^{n} d(u_i, v_i)^{\frac{1}{n}} \right). \]

**Proposition 2.5.** Suppose $\bigwedge_C$ is a $q-$ array lattice and $v = (v_1, v_2, \ldots, v_n)^e \in \mathbb{R}^n$ is the received vector. Let $v \in \mathbb{R}^n$, $C \in F_2^n[x]/\langle x^n - 1 \rangle$ and $c \in C, c = (c_1, c_2, \ldots, c_n)^e$, $0 \leq c_i < q$, a neighbor codeword to $u$. Considering the induced metric $d_c \in F_2^n[x]/\langle x^n - 1 \rangle$ another neighbor $z \in \bigwedge_C$ is given by $(z_1, z_2, \ldots, z_n)^e$ where $z_i = c_i + qA_i$ for $A_i = |\frac{u_i - v_i}{q}|$ for $i = 1, 2, 3, \ldots, n$.

**Proof**
We should show that if $u \in C$ and $z = u + qA$, for $A_i = |\frac{u_i - v_i}{q}|$, then $d(v, z) = d_c(v, z)$. We know that $c \in C$ satisfies $d_c(v, c) = \min \{ d_c(v, u), u \in C \}$. For $A_i = |\frac{u_i - v_i}{q}|$ it follows that $d(v, c + qA_i) = d_c(v, c) \leq \min \{ d(v, u + qe), u \in C, e \in F_2^n[x]/\langle x^n - 1 \rangle \}$. Hence $c + qA_i$ is the neighbor of $\bigwedge_C$ that minimizes the distance $d_c(v, u)$. 

Our next problem is the characterization of perfect codes generated by the candidate ring.

We already know that perfect codes satisfy the sphere packing bound with equality, (see Hall [5]).

**Proposition 2.6.** Given the range $1 \leq n < \infty$ perfect codes exist in the polynomial ring $F_2^n[x]/\langle x^n - 1 \rangle$ induced by the metric $d_c$ for $\kappa_c = 1$ and any $\ell = 2n + 1$.

**Proof**
If $n = 1$ the result is clear. Suppose $1 < n < \infty$. The inequality $|u_1|^n + \cdots + |u_n|^n \leq 1$ has $2n + 1$ integer solutions namely $u_i = \pm 1$ and $u_j = 0$ for all $j \neq i$ and $u_i = 0$ for all $i$. Define $\mathcal{S}_n(n, 1)$ to be the number of points in $F_2^n[x]/\langle x^n - 1 \rangle$ inside a sphere centered at the origin. Then $\mathcal{S}_n(n, 1) = 2n + 1 = \mathcal{S}_1(n, 1)$. But there exists at least one perfect code $C \subseteq F_2^n[x]/\langle x^n - 1 \rangle$ in the metric $d_c$ satisfying the proposition. It follows that this code must also be perfect in the metric $d_c$ for any $1 < n < \infty$, because $|C| \leq \mathcal{S}_n(n, 1) = |C| \leq \mathcal{S}_1(n, 1) = 2^n$. 

The perfect codes characterized by Proposition 2.6 are trivial. The next problem is to characterize non-trivial perfect codes of the candidate polynomial ring.
Proposition 2.7. For an odd integer \( \alpha > 1 \in F_2^n [x] / (x^n - 1) \) and any integer \( \beta > 1 \in F_2^n [x] / (x^n - 1) \), there exists a non-trivial perfect code \( C \subseteq F_2^n [x] / (x^n - 1) \) in the metric \( d_\infty(u, v) \) if and only if \( q = \alpha \beta \).

Proof

By the sphere packing bound [1] we know that a code \( C \subseteq F_2^n [x] / (x^n - 1) \) with minimum distance \( 2\kappa + 1 \) is perfect if and only if:

\[
| C | = (2\kappa + 1)^n q_n.
\]

This implies that \( | C | = q_n \). This means \( q \) must have an odd factor and so \( q \neq 2^n \). If \( q \) is prime then \( 2\kappa + 1 = q \) which gives a perfect trivial code. Thus there is no perfect code for prime \( q \) or composite \( q \), a power of 2.

Suppose \( q = \alpha \beta \). Let the code \( C \) be generated by the vectors 
\[
\{ (\alpha, 0, \ldots, 0), (0, \alpha, 0, \ldots, 0), \ldots, (0, \ldots, 0, \alpha) \} \in C \subseteq F_2^n [x] / (x^n - 1). \]

Therefore \( | C | = \beta^n \). Suppose \( e \in F_2^n [x] / (x^n - 1) \). If \( e = \beta n + v \), for \( 0 \leq v < \beta \) then \( e(0, \ldots, \alpha, 0, \ldots, 0) = v(0, \ldots, \alpha, \ldots, 0) \). In this case the minimum distance \( \kappa_c = \min \{ d_\infty(u, v), u, v \in C, u \neq v \} = \alpha \). This implies that \( \kappa_c = \frac{\alpha - 1}{2} \). Since \( \kappa_c = 2n + 1 \) implies that \( | C | \kappa_c = \alpha^n \beta^n = q^n \) for \( 1 < | C | < q^n \). This code is perfect and non-trivial.

Remark 2.1. There are no perfect codes of length \( n \in \mathbb{N} \) and \( \kappa_c > 1 \).

Let \( W_{11} \) denote a polynomial code generated by 
\[
b(x) = x^{10} + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1.
\]

Its generator matrix is 
\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]

and hence \((11, 1)\) is a repetition code.

The cyclic code \( C_{11} \) with generator polynomial \( a(x) = x + 1 \) is \((11, 10)\) code. From the generator polynomial we obtain a generator matrix which can be transformed into a systematic generator matrix
\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1
\end{bmatrix}
\]

Hence \( C_{11} \) is isometric to a parity check code. It consists of all even weight vectors in \( F_2^{11} \).
Figure 1: Lattice diagram of the generators of \( x^{11} - 1 \)

**Definition 2.2.** [7] A geometric lattice is a regular arrangement of points in an \( n \)-dimensional Euclidean space. A polyhedron is a solid in three dimensions whose surface is made up of a number of polygonal surfaces.

Geometrically Figure 1 is a lattice diagram with 4 lattice points. In this research each lattice point is a codeword. The shape of this geometric lattice is a rhombus.

Let \( W_{15} \) denote a cyclic code which is generated by \( d_1(x)d_2(x)d_3(x)d_4(x) = (x^2 + x + 1)(x^4 + x + 1)(x^4 + x^3 + 1)(x^4 + x^3 + x^2 + x + 1) = x^{14} + x^{13} + x^{12} + x^{11} + x^{10} + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1 \). Its generator matrix is \[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]
and hence \( W_{15} \) is a (15, 1) repetition code. The cyclic code \( S_4 \) with generator polynomial \( a(x)d_1(x)d_2(x)d_4(x) = x^{11} + x^{10} + x^9 + x^8 + x^6 + x^4 + x^3 + 1 \) is a (15, 4) code which is isometric to \( S_4 \). The cyclic code \( C_{15} \) with generator polynomial \( a(x) = x + 1 \) is a (15, 14) code. From its generator polynomial we obtain a generator matrix that can be transformed using elementary row transformations into the systematic generator matrix
Hence $C_{15}$ is isometric to a parity check code. It consists of all even weight vectors in $\mathbb{F}_{15}^2$.

The cyclic code $H_8$ generated by $d_3(x)d_4(x) = x^8 + x^5 + x^3 + 1$ is $(15, 7)$ code with generator matrix

$$
\begin{bmatrix}
1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
$$

Now $H_8^\perp$ has the generator polynomial $a(x)d_1(x)d_2(x) = x^7 + x^3 + x + 1$ so that $H_8^\perp$ is the simplex code $S_8$, hence $H_8$ is a Hamming code.

\]

Generator matrix for $d_4(x)$

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]
Geometrically this is a closed lattice diagram with 57 lattice points. It is a polyhedron with 57 vertices.

**Theorem 2.3.** Let $W_n$ denote a code with generator polynomial $g(x) = g_0(x) + g_1(x) + g_2(x^2) + \ldots + g_{n-k}(x^{n-k})$, the generator matrix is given by

$$G = \begin{bmatrix} g_0 & g_1 & \cdots & g_{n-k} & 0 & 0 & \cdots & 0 \\ 0 & g_0 & g_1 & \cdots & g_{n-k} & 0 & \cdots & 0 \\ 0 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 & \cdots & g_{n-k} \end{bmatrix}$$

**Proof**
We should show that:
(i) $g_0(x) + g_1(x) + g_2(x^2) + \ldots + g_{n-k}(x^{n-k})$ forms a basis of $W_n$.
(ii) $\dim(W_n) = k$.

For part (i) the vectors $g_0(x), g_1(x), g_2(x^2), \ldots, g_{n-k}(x^{n-k})$ are linearly independent. If not we must have a set of coefficients $\{\alpha_i\}$ such that $\alpha_0 g_0(x) + \alpha_1 g_1(x) + \alpha_2 g_2(x^2) + \ldots + \alpha_k g_{n-k}(x^{n-k}) = 0$. But this product has degree $k - 1 + n - k = n - 1 < n$, which cannot be $0 \mod(x^n - 1)$ unless all the $\alpha_i = 0$. Suppose we have $w(x)$ in $W_n$, then $w(x) = \alpha(x) g(x)$. Assume $\alpha(x)$ has degree $< k - 1$. Then $w(x)$ can be written as a linear combination of $x^i g(x)$ for $0 < i < k - 1$. The set of all the linear combinations $\{x^i g(x)\}$ is a basis for $W_n$.

For part (ii) suppose we have two polynomials $p_1(x) \neq p_2(x)$ with degree $p_i(x) \leq k - 1$ (for $i = 1, 2$) and $g(x)p_1(x) \neq g(x)p_2(x)$. The set $\tau = \{g(x)p(x) : p(x) \in F_q^n(x)/\langle x^n - 1 \rangle, \text{ degree } p(x) \leq k - 1\}$ has $q^k$ elements and is a subset of the ideal $\langle g(x) \rangle$.

Conversely for any codeword $g(x)r(x)$ (for some $r(x) \in F_q^n(x)/\langle x^n - 1 \rangle$), we have $g(x)r(x) = y(x)(x^n - 1) + z(x)$ (for some $z(x) \in F_q^n(x)/\langle x^n - 1 \rangle$). This means $z(x) = g(x)r(x) - y(x)(x^n - 1)$. Therefore $g(x)$ divides $z(x)$. Let $z(x) = g(x)t(x)$ for some polynomial $t(x) \in F_q^n(x)/\langle x^n - 1 \rangle$. This implies that degree $t(x) < k$ and hence $z(x) \in \tau$. Equivalently, $\tau = \langle g(x) \rangle$. Hence the dimension of the code is given by $\log_q|\tau| = k$.

**Proposition 2.8.** Let $S_k(q)$ be a simplex code. Then $S_k(q)$ is a constant weight code with parameters $[(q^k - 1)/q - 1, k, q^{k-1}]$.

**Proof**
Let $H_k^+(q)$ be a Hamming code. We know that the simplex code $S_k(q)$ and the Hamming code $H_k^+(q)$ are dual codes. $H_k^+(q)$ is a parity check matrix of $H_k^-(q)$ and the generator matrix of $S_k(q)$. 

Consider a parity check matrix $H_k(q)$ with redundancy $k$. The rank of this matrix = dimension = $k$. Let $u$ be a non zero codeword of the simplex code $S_k(q)$. We have $u - mH_k(q)$ for some non-zero $m \in F_q^n[x]/(x^n - 1)$ . Let $h_i^T(q)$ be the $i^{th}$ column of $H_k(q)$ (for $i = 1, 2, 3,...$). Then $\Sigma u_i = 0$ if and only if $mh_i = 0$. Let $mv = 0$ for some $v \in F_q^n[x]/(x^n - 1)$ be a non-trivial homogeneous linear equation. This equation has $q^{k-1}$ solutions. The solutions $(q^{k-1})/q - 1$ such that $v^T$ is a column of $H_k(q)$ is a non-zero multiple of $v^T$. Hence the number of zeros of $u$ is $(q^{k-1} - 1)/q - 1$. Therefore the weight of $u$ is the number of non-zeros which is $q^{k-1}$.

**Proposition 2.9.** For a polynomial code $P_c \in F_2^n[x]/(x^n - 1)$ the following statements are equivalent

(i) Hamming weight of $P_c$ is isomorphic to the homogeneous weight.

(ii) Homogeneous weight of $P_c$ is isomorphic to the Hamming weight.

**Proof**

(i)\(\Rightarrow\) (ii) Let $f^n(u) = f(x_1) + ... + f(x_n)$ for all $f^n(u) \in I$ where $I$ is an ideal in $F_2^n[x]/(x^n - 1)$ . Then;

\[
(\Sigma f^n)u = \frac{1}{R_n u} \Sigma v \in R_n f^n v
\]

for all $f^n(v) \in R_n$ and $R_n = F_2^n[x]/(x^n - 1)$

\[
= \frac{1}{R_n u} \Sigma v \in R_n \Sigma i=1^n f^n (v_i)
\]

\[
= \frac{1}{R_n u} \Sigma i=1^n \Sigma v \in R_n f^n (v_i)
\]

\[
= \Sigma i=1^n (\Sigma f)(v_i)
\]

\[
= (\Sigma f)^n(u)
\]

(ii)\(\Rightarrow\) (i) Let $f^n(v) = f(x_1) + ... + f(x_n)$ for all $f^n(v) \in I$ where $I$ is an ideal in $F_2^n[x]/(x^n - 1)$ . Then;

\[
(\Sigma f^n)v = \frac{1}{R_n v} \Sigma u \in R_n f^n u
\]

for all $f^n(u) \in R_n$ and $R_n = F_2^n[x]/(x^n - 1)$

\[
= \frac{1}{R_n v} \Sigma u \in R_n \Sigma i=1^n f^n (u_i)
\]

\[
= \Sigma i=1^n \frac{1}{R_n v_i} \Sigma u \in R_n f^n (v_i)
\]

\[
= \Sigma i=1^n (\Sigma f)(v_i)
\]

\[
= (\Sigma f)^n(v)
\]

**Proposition 2.10.** Let $W_n$ be a cyclic code with a check polynomial $h(x) = h_0 + h_1(x) + ... + h_k x^k$. Then $W_n$ has dimension $k$ with the parity check matrix
given by:
\[ H = \begin{bmatrix} h_0 & h_{k-1} & \ldots & h_k & 0 & \ldots & 0 \\ 0 & h_0 & h_{k-1} & \ldots & h_k & 0 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & 0 & h_k & h_{k-1} & \ldots & h_0 \end{bmatrix} \]

Proof
Let the degree of the generator matrix = \( n - k \). The dimension of this code is \( k \). Let \( u = c_0 + c_1(x) + c_2(x^2) + \ldots + c_n(x^{n-1}) \) for some \( u \in F^n_2[x]/(x^n - 1) \). Then \( u(x)h(x) = 0 \). For \( d = k, k+1, \ldots, n-1 \) we have \( \Sigma c_i h_j = 0 \) (for \( i + j = d \)). These code-vectors are orthogonal to the linear combinations of the rows of \( H \). Hence \( C^\perp \) contains the span of the rows of \( H \). Since \( hk = 1 \), the rank of \( h = n - k \). This generates a linear subspace of \( C^\perp \), implying that \( H \) is the parity check matrix for the check polynomial \( h(x) \).

2.1 Syndromes of the simplex codes in the candidate ring

Definition 2.3. [1] Let \( C \) be an \((n, \kappa, d)\) code over \( F^n_2[x]/(x^n - 1) \) and let \( H \) be a parity check matrix for \( C \). For any \( w \in F^n_2[x]/(x^n - 1) \) the syndrome of \( w \) is the codeword \( S(w) = wH^T \in F_{2^{n-k}}^2[x]/(x^n - 1) \).

Proposition 2.11. [1] Let \( u, v \in C \), where \( C \) is a codeword generated by \( F^n_2[x]/(x^n - 1) \). The following statements are equivalent.
(i) \( u \) and \( v \) are in the same coset.
(ii) \( u \) and \( v \) have the same syndrome

Proof
(i)\(\Rightarrow\) (ii). Suppose \( u \) and \( v \) belong to the same coset. Then \( u = z_1 + e \) and \( v = z_2 + e \) for \( z_1, z_2 \in C \) and \( e \in F^n_2[x]/(x^n - 1) \). The syndrome corresponding to \( u \) is given by \( Hu^T = H(z_1 + e)^T = He^T \).

The syndrome corresponding to \( v \) is given by \( Hv^T = H(z_2 + e)^T = He^T \). Hence the syndrome of \( u \) and \( v \) are the same.

(ii)\(\Rightarrow\) (i). Suppose \( u \) and \( v \) have the same syndrome. Then \( Hu^T = Hv^T = H(u-v)^T = 0 \implies (u-v) \in C \). Since \( u-v \) is a codeword then \( u \) and \( v \) must belong to the same coset.
